

Overt Distributivity in Algebraic Event Semantics*

Lucas Champollion

May 28, 2014

Abstract

Adnominal and adverbial distributive elements are known to differ across languages as to whether they can only distribute over individuals mentioned in the same sentence, or also over pragmatically salient occasions that have not been mentioned. Those that can also be used as distributive determiners, such as English *each*, never allow distribution over occasions (Zimmermann, 2002b). I explain this pattern, and the behavior of distance-distributivity more generally, in a surface-compositional theory that imports ideas formally relates the differences in overt distributive elements to those between distributivity operators posited by Link (1983) and Schwarzschild (1996). I achieve surface compositionality by formulating the theory in algebraic event semantics (Krifka, 1998).

Keywords: distance-distributivity, crosslinguistic semantics, algebraic semantics, adnominal *each*, adverbial *each*, quantifier float, covers

1 Introduction

This paper presents a surface-compositional theory of distance distributivity that relates adnominal and adverbial distributive elements, atomic and cover-based distributivity, and distributive determiners to each other. This is one of two self-contained papers that can be read individually but that form a coherent whole. This paper focuses on overt distributivity and the other one on covert distributivity. Both kinds of distributivity are illustrated in the following example:

*For helpful discussions and comments, I am grateful to Chris Barker, Benjamin Bruening, Dylan Bumford, Seth Cable, Robert Henderson, Chris LaTerza, Anna Szabolcsi, Linmin Zhang, Malte Zimmermann and to the audiences of the Stuttgart 2011 workshop on distributivity, the Amsterdam Colloquium 2011, an audience at the University of Potsdam, and to members of my 2013 NYU seminar on algebraic semantics, where earlier versions of this paper were presented. I thank Linmin Zhang for collecting judgments via Mechanical Turk pilot studies. For native speaker judgments, I thank my consultants Isaac Bleaman, Heather Burnett, Tuğba Çolak, Liz Coppock, Hana Filip, Gianina Iordăchioaia, Zack Jagers, Songhee Kim, Sonia Kasyanenko, Jeremy Kuhn, Chigusa Kurumada, Roumyana Pancheva, Kjell Johan Sæbø, and Yohei Oseki. This paper builds in part on some earlier work of mine, for which I am indebted to many people and institutions as indicated there (Champollion, 2012, 2013).

- (1) a. The girls each wore a black dress.
- b. The girls wore a black dress.

In sentence (1a), the adverbial distributive element *each* distributes the predicate *wear a black dress* over the individual girls and leads to the entailment that each of the girls in question wears a black dress. Sentence (1b) is interpreted in the same way, even though there is no *each*. The ability of verb phrases to distribute in the absence of an overt distributive element has been attributed to what is traditionally called the D operator, a silent counterpart of adverbial *each* (Link, 1987; Roberts, 1987).

The purpose of this paper and its counterpart is to bring together several strands of research on phenomena related to the semantics and pragmatics of distributivity in natural language. One of these strands deals with overt distributivity, which is crosslinguistically often expressed via adverbials and adnominals, such as English *each* and German *jeweils*. Such elements differ with respect to whether they are restricted to distribution over individuals mentioned in the same sentence, or whether they can also distribute over pragmatically salient occasions that need not have been explicitly mentioned. It has been motivated by the properties of adverbial *each* and its adnominal and determiner counterparts both in English and other languages (Zimmermann, 2002b). As we will see, the meanings of these elements varies in ways that sometimes require them to distribute over individuals, such as in the case of *each*, and in other cases allow them to distribute over salient parts of spacetime, such as in the case of *jeweils*. This is the focus of this paper.

The other strand studies the properties of silent distributivity operators such as the one arguably present in (1b). Covert phrasal distributivity has been at the center of a long debate as to whether it always involves distribution over atoms – singular individuals – or whether it can also involve distribution over nonatomic entities (Lasnik, 1989; Gillon, 1990). This is the focus of the counterpart of this paper. I will reserve the term *D operator* for distributivity operators that always distributes over atoms. As for the nonatomic version of the operator, whose meaning may be paraphrased as *each salient part of*, I will refer to it as the Part operator (Schwarzschild, 1996).

As this sketch already suggests, overt and covert distributivity share many similarities. This gives rise to similar questions both in the overt and in the covert case. Can a distributivity operator only distribute down to singular entities or also to plural entities? Do these entities need to be of a certain size or “granularity”, and can this size vary from operator to operator? Must these entities have been overtly mentioned in the sentence and thereby contributed by semantic means, or can they also be supplied by the context via pragmatic means?

A unified semantic analysis of distributivity should make it apparent which aspects of the meanings of various distributivity operators are always the same, and along which dimensions these meanings can differ. The semantic variation across distributivity related elements should be captured by parameters. The resulting system should be fully formalized and explicit.

This paper, together with its counterpart, contributes towards these goals. By combining ideas from algebraic semantics and event semantics, the two papers provide a framework in which the split in overt distance-distributive elements can be related

to the debate in the literature on covert distributivity. In this framework, the various uses of *each* in English are all lexically related to the distributivity operator, either in its semantic, atomic form as defined by Link (1987) or in its pragmatic, saliency-related form as defined by Schwarzschild (1996). These various uses of *each* and these silent operators share some part of their meanings with each other and with their counterparts across languages is captured by deriving them from related distributivity operators which differ only in possible settings of two parameters and the ranges of values they allow for them. One parameter indicates the dimension in which distributivity takes place. This can be a thematic role in some semantic instances of distributivity, or a spatial or temporal dimension in other instances. The other parameter indicates the size of the entities over which distributivity takes place, such as atoms or salient amounts of space or time. These parameters interact with each other against the background of assumptions about the metaphysics of natural language. For example, time is assumed to be either nonatomic or in any case to not make its atoms available to the semantics of natural language. As a result, when the first parameter is set to time, the second cannot be set to anything involving atoms, because time does not provide any atoms to distribute over. This simple idea turns out to explain and connect a range of superficially unrelated facts observed in various places in the literature. It is situated within a broader framework that connects it to aspect and measurement under the name of strata theory (Champollion, 2010).

In this paper, I provide a view on the seemingly noncompositional behavior of distance-distributive elements on which they look much more well-behaved than might be expected. In particular, the analysis is surface-compositional, reuses many independently motivated assumptions, and avoids unusual semantic mechanisms such as index-driven and crosswise lambda abstraction (Zimmermann, 2002b). I also avoid nonstandard concepts such as distributive polarity items (Oh, 2001, 2006). The analysis is placed in the context of algebraic event semantics. This allows us to formally model the relations between distribution over individuals and over events, as well as those between distribution over atoms and over nonatomic parts. The paper provides a formal framework for algebraic event semantics and makes an explicit proposal for a compositional process.

When we move to algebraic event semantics, the theory of distributivity operators developed by Link (1987) and extended by Schwarzschild (1996) turns out to have to be adjusted for a number of reasons, which is done in the other paper. As shown by the following examples, the Neo-Davidsonian event semantic setting gives us the ability to think of the D and Part operators as being coindexable with different thematic roles. This allows us to capture through a simple change in coindexation the kinds of configurations that have otherwise been taken to require type-shifting-based reformulations of these operators (Lasnik, 1998):

- | | | | |
|-----|----|--|--------------------------|
| (2) | a. | The first-year students D(took an exam). | <i>Target: agent</i> |
| | b. | John D(gave a pumpkin pie) to <u>two girls</u> . | <i>Target: recipient</i> |

The reformulation of the distributivity operators in the other paper provides the groundwork on which I build in this paper in order to formally relate this ambiguity to the one observable in examples like the following:

- (3) The boys told the girls two stories each. *Target: agent*
(two stories per boy)
- (4) The boys told the girls two stories each. *Target: recipient*
(two stories per girl)

The theoretical picture that has been sketched so far, and that is developed below and in the other paper, provides us with a way to formulate commonalities and differences across instances of distributivity in natural language. Individual elements can be analyzed as being hard-wired for certain parameter values, so that, for example, the difference between Link’s and Schwarzschild’s operators, as well as that between *each* and *jeweils*, can be described in terms of whether the value of the granularity parameter is prespecified to *Atom* or can be filled in by context. In this way, overt and covert instances of distributivity fit together and into distributivity theory more generally.

To develop this picture, Section 2 starts by describing relevant facts and generalizations about overt instances of distributivity across languages, drawing largely on the overview of distance-distributivity in Zimmermann (2002b). The two strands – overt and covert distributivity – are brought together in Section 3, which develops a surface-compositional account of overt distance distributivity. Certain typological facts about the range of meanings of overt distributive elements, described by Zimmermann (2002b) and in Section 2, are explained in Section 4. I compare the present analysis with Zimmermann (2002b) in Section 5. Section 6 shows how to extend the analysis to the case when English *each* modifies a prepositional phrase. Section 7 concludes.

2 Overt Distributivity

I propose that distance-distributive elements should be essentially thought of as versions of the D and Part operators. In this point, I loosely follow a proposal made for German *jeweils* and its short form *je* by Link (1986, 1987). While Link did not give a compositional implementation and did not consider the crosslinguistic picture, this paper can be seen, in a way, as an update to these early ideas which benefits from later work on algebraic semantics, nonatomic distributivity, and compositional implementations as discussed in the other paper.

This section presents the empirical basis for this paper. Distributive elements have different syntactic uses and different meanings crosslinguistically. In English, the distributive quantifier *each* can be used in at least three ways, which I will refer to as adnominal, adverbial, and determiner *each* respectively:

- (5) a. **Adnominal each:** Two men have carried three suitcases *each*.
b. **Adverbial each:** Two men have *each* carried three suitcases.
c. **Determiner each:** *Each* man has carried three suitcases.

There are many terms for these three uses. Adnominal *each* has also been called shifted (Postal, 1974), an anti-quantifier (Choe, 1987), binominal (Safir and Stowell, 1988), or ditransitive (Roberts, 1987). Adverbial *each* has also been called floated (Choe, 1987). Determiner *each* is also called prenominal (Safir and Stowell, 1988). For the purpose of this paper, I set aside the use of *each* in other constructions, notably the reciprocal

each other and the partitive *each of the men*. On the connection between reciprocals and *each*, see for example LaTerza (2014a,b). I will refer to the noun phrase *two men* in (5a) and (5b) as the antecedent of *each*, and to the noun phrase *three suitcases* in (5a) as the host of adnominal *each*.

I will refer to adnominal and adverbial *each* and to similar elements across languages as distance-distributive elements. That term is taken from Zimmermann (2002b). There is a slight difference in terminology: Zimmermann reserves the term *distance distributivity* for adnominal elements while I use it for both adnominal and adverbial elements, because adverbial *each* can be separated from its antecedent by an auxiliary, as shown in (5b).

Adnominal *each* can be shown by movement tests to form a constituent with its host (Burzio, 1986; Safir and Stowell, 1988). Distance-distributive elements like it are sometimes thought of as a challenge for compositional semantics, because their interpretations are similar to those of distributive determiners even though their surface syntactic structure appears to be fundamentally different (Oh, 2001, 2006). For example, adnominal *each* in the object of sentence (5b) is contained in the constituent over which it distributes, namely the verb phrase. This by itself is similar to the challenge represented by quantifiers in object position, and the standard solutions to that challenge are available in that case. For example, one can lift the type of the quantifier or the verb in order to give the quantifier scope over the verb phrase (Hendriks, 1993; Barker, 2002). I will follow the same general strategy in the formal analysis below.

As we have seen in the pair of examples in (3) and (4) above, adnominal *each* can target different antecedents. This dependency is generally regarded as a case of ambiguity rather than underspecification, and I will follow this view. For a dissenting opinion, according to which the sentence has a single meaning that can be paraphrased as *two stories per participant*, see Cable (2014). There are syntactic constraints on the distribution of adnominal *each* with respect to its antecedent, and the dependency has been variously argued to be similar to that of reflexive pronouns with respect to their antecedents (Burzio, 1986; Safir and Stowell, 1988) or to that of traces of noun phrases that undergo raising with respect to these noun phrases (Sportiche, 1988). Similarly, adverbial *each* has been variously claimed to be related to its antecedent by movement, in the sense that it modifies the trace of its antecedent, or to be base-generated, in which case its relation to its antecedent can be taken to be anaphoric. For an overview of these conflicting claims and their implications, see Bobaljik (2001). Since the nature of the dependency between adnominal and adverbial *each* and their antecedents is not in the focus of this paper, I will not take a strong position on it. In the formal theory to be developed below, I will represent it via coindexing of thematic relations, which is more in line with anaphora-based accounts than with movement-based ones. In this, I follow previous semantic analyses that interpret adnominal *each* without any movement, such as Zimmermann (2002b). Should the movement-based view turn out to be the correct one, the syntax-semantics interface may need to be modified accordingly, for example by incorporating elements from the movement-based theory of Cable (2014).

Turning now to other languages, adnominal and adverbial *each* are translated in German by one word, *jeweils* (Moltmann, 1997; Zimmermann, 2002b). Determiner *each*,

however, is translated by another word, *jed-*. I gloss distance-distributive elements as DIST since, as we will see, they have a wider range of readings than *each*. Example (6a) is adnominal, example (6b) is adverbial, and example (6c) contains a determiner. Though adverbial and adnominal *jeweils* take the same surface position in (6a) and (6b), they can be teased apart syntactically, as discussed in Zimmermann (2002b).

- (6) a. Die Jungen haben [*jeweils* [drei Koffer]] getragen.
 The boys have DIST three suitcases carried.
 b. Die Jungen haben [*jeweils* [drei Koffer getragen]].
 The boys have DIST three suitcases carried.
 c. *Jeder*/**jeweils* Junge hat drei Koffer getragen.
 Each.sg.n/DIST boy has three suitcases carried.

As we will see, *each* and *jeweils* generalize to two classes of distance-distributive elements across languages. *Each*-type distance-distributive elements can also be used as determiners. *Jeweils*-type distance-distributive elements cannot double as determiners. Some languages have distance-distributive elements which can also function as distributive determiners, as in English, and others are like German in that they have no such elements (Zimmermann, 2002b). Across these languages, Zimmermann observes that distance-distributive elements which can also be used as determiners (e.g. *each*) always distribute over individuals, as determiners do. In contrast, many of those distance-distributive elements which are formally distinct from determiners (e.g. *jeweils*) can also distribute over salient occasions, that is, over chunks of time or space.

Let me illustrate this observation by using German *jeweils*, a distance-distributive element which cannot double as a distributive determiner. *Jeweils* can distribute over individuals like English *each*, but also over spatial or temporal occasions, as long as context provides a salient set of such occasions. I call this the occasion reading. It corresponds to what is also called the *spatial key reading* and the *temporal key reading* (Balusu, 2005; Balusu and Jayaseelan, 2013). I leave open the question of whether or not the spatial and temporal cases should be distinguished as two separate readings. Another, less theory-neutral term for the occasion reading is *event-distributive reading* (Oh, 2001, 2006). Zimmermann (2002b) uses the term *adverbial reading* for it. This term is misleading, because it suggests that only the adverbial use of *jeweils* can give rise to this reading. But adnominal *jeweils* can give rise to it as well (Zimmermann, 2002b, ch. 5). For example, in (7), *jeweils* is part of the subject DP and is therefore adnominal. However, as shown by the paraphrase, this instance of *jeweils* distributes over occasions, not over individuals.

- (7) *Jeweils* zwei Jungen standen Wache.
 DIST two boys stood watch.
 ‘Each time, two boys kept watch.’

The following examples illustrate the occasion reading. Sentence (8) is ambiguous between a reading that distributes over individuals – the ones of which their plural subject consists, (8a) – and one that distributes over occasions (8b).

- (8) Die Jungen haben jeweils zwei Affen gesehen. (*German*)
 The boys have DIST two monkeys seen.
 a. 'Each of the boys has seen two monkeys.'
 b. 'The boys have seen two monkeys each time.'

While the former reading is always available, the latter requires a supporting context. That is, when (8) is uttered out of the blue, it only has the reading (8a). The reading (8b), by contrast, is only available in contexts where there is a previously mentioned or otherwise salient set of occasions, such as contexts in which the boys have been to the zoo on several previous occasions.

Unlike *each*, *jeweils* can also occur with a singular subject, as in (9), which only has an occasion reading.

- (9) Hans hat jeweils zwei Affen gesehen. (*German*)
 Hans has DIST two monkeys seen.
 'Hans has seen two monkeys on each occasion.'

This sentence is odd out of the blue, and it requires supporting context in the same way as reading (8b) does. Its other potential reading would involve vacuous distribution over only one individual, Hans, and is presumably blocked through the Gricean maxim of manner "Be brief" or whatever else prevents vacuous distributivity.

While *jeweils* allows distribution both over individuals and over salient occasions, this is not the case for all distance-distributive elements (Zimmermann, 2002b). Across languages, many adnominal distance-distributive elements can only distribute over individuals. For example, English adnominal *each* lacks the occasion reading:

- (10) The boys saw two monkeys each.
 a. *Available*: 'Each of the boys saw two monkeys.'
 b. *Unavailable*: 'The boys saw two monkeys on each occasion.'

When adnominal *each* is used in a sentence whose subject is singular, distribution over individuals is not possible, again presumably for pragmatic reasons:

- (11) *John saw two monkeys each.

Unlike (9), this sentence lacks an occasion reading, even with supporting context. To make the occasion reading surface, one needs to add an overt noun like *time*:

- (12) John saw two monkeys each time.

We have seen that English *each* also differs from German *jeweils* in that only the former can also be used as a determiner. Zimmermann reports the following generalization (Zimmermann, 2002b):

- (13) **Zimmermann's generalization:** All *each*-type distance-distributive elements (i.e. those that can also be used as determiners) can only distribute over individuals. This contrasts with *jeweils*-type distance-distributive elements, many of which can also distribute over salient spatial or temporal occasions.

This generalization is based in part on the following examples, which show that distance-distributive elements in Dutch, French, Italian, Japanese, Norwegian, and Russian all behave like English *each* in two ways: They can also be used as distributive determiners, and they lack the occasion reading except when an extra noun *time* is added.

- (14) De jongens hebben *elk* twee boeken gelezen.
the boys have each two books read
'The boys have read two books each.' (Dutch)¹
- (15) *Elk* jonge heeft twee boeken gelezen.
each boy has two books read
'Each boy has read two books' (Dutch)²
- (16) *Elk* *(keer) zijn twee jongens gekomen.
each time have two boys come
'Each time, two boys came.' (Dutch)³
- (17) Les professeurs ont lu deux livres *chacun/chaque*.
the professors have read two books each
'The professors have read two books each.' (French)⁴
- (18) *Chaque* professeur a lu deux livres.
each professor has read two books
'Each professor has read two books.' (French)⁵
- (19) Peter a lu deux livres *chaque* *(fois) / **chac-un(e)*(fois).
Peter has read two books each time
'Peter read two books each time.' (French)⁶
- (20) I ragazzi comprarono un libro *ciascuno*.
the boys bought a book each.sg.m
'The boys bought one book each.' (Italian)⁷
- (21) *Ciascun* ragazzo ha comprato due salsicce.
each boy has bought two sausages
'Each boy has bought two sausages.' (Italian)⁸
- (22) Peter ha vinto *ogni* *(volta) / **ciascuno/a* (volta).
Peter has won each time
'Peter won each time.' (Italian)⁹

boys.nom bought two sausage.gen.sg each
'The boys bought two sausages each.'
(Russian)¹⁷
- (31) *Kazhdjy* mal'chik kupil dve sosiski.
each boy bought two sausages
'Each boy bought two sausages'
(Russian)¹⁸
- (32) Petja pokupal dve sosiski *kazhdjy* *(raz).
Petja buy.perf two sausage each (time)
'Peter bought two sausages each time.'
(Russian)¹⁹

Zimmermann's generalization goes only one way, or in other words, the "if" cannot be strengthened to "if and only if". While every distance-distributive element that can be used as a determiner lacks the occasion reading, the opposite is not the case. For

¹⁰Sakaguchi (1998, p. 115, ex. 1) quoted in Zimmermann (2002b, p. 41)

¹¹Sakaguchi (1998, p. 4, ex. 7)

¹²Chigusa Kurumada, p.c. to the author. Kurumada comments that the sentence without *de* feels like an elliptical version of the sentence with *de*.

¹³Satoshi Tomioka, p.c. to Zimmermann (2002b, p. 45)

¹⁴Vangsnes, p.c. to Zimmermann (2002b, p. 40)

¹⁵Zimmermann (2002b, p. 44)

¹⁶Kjell Johan Sæbø, p.c. to the author

¹⁷Borik, p.c. to Zimmermann (2002b, p. 41)

¹⁸Borik, p.c. to Zimmermann (2002b, p. 44)

¹⁹Sonia Kasyanenko, p.c. to the author

example, the Romanian distance-distributive elements *cîte* lack the occasion reading, but cannot be used as a determiner. This is illustrated in the following examples:

- (33) Doi oameni au cărat *cîte* trei valize.
two men have carried each three suitcases
'Two men have carried three suitcases each.' (Romanian)²⁰
- (34) **Cît(e)* student a plecat.
each student has left.
Intended: 'Each student has left.' (Romanian)²¹
- (35) *Petru a cîştigat *cîtă/cîte* (dată).
Peter has won each.f/each.adv time.
Intended: 'Peter won each time.' (Romanian)²²

Zimmermann discusses the fact that *sorezore* differs formally from the distributive determiner-quantifier *wh... + mo*, which is illustrated in (36). However, *sorezore* can be used in the position of a determiner, as example (24) shows.

- (36) *Dono* gakusei-mo sooseezi-o hutatu katta.
which student-MO sausage-acc two-cl bought
'Every student bought two sausages.' (Japanese)²³

While these are counterexamples to the "only if" direction of Zimmermann's generalization (Romanian is one as we have seen, and Zimmermann presents Japanese as another one based on the assumption that *sorezore* cannot be used as a determiner), that direction still describes a tendency. In addition to German *jeweils*, adnominal distance-distributive elements in Bulgarian, Czech, and Korean have occasion readings, and they cannot be used as determiners. This is shown below. Most of these observations, and their implications on Zimmermann's generalization, are due to Zimmermann (2002b). The Korean case is also discussed in depth by Choe (1987) and by Oh (2001, 2006).

- (37) John i Mary kupiha *po* edna tetradka.
John and Mary bought each one notebook
'John and Mary bought one notebook each.' (Bulgarian)²⁴
- (38) *Vsjako*/**Po* momche kupi dve jabulki.
each boy bought two sausages
'Each boy bought two sausages.' (Bulgarian)²⁵
- (39) Mary byaga *po* 5 mili predi zakuska.
Mary runs each 5 miles before breakfast
'Mary runs 5 miles before breakfast (every morning).' (Bulgarian)²⁶

 ‘I bought a balloon (each time / each day / at each store).’ (Korean)³²

Many languages express adnominal distance distributivity by a bound morpheme (either an affix or a reduplicative morpheme) that attaches to a numeral (Gil, 1982). In this category, on the one hand, we find cases where this process does not give rise to occasion readings, such as Hungarian (Farkas, 1997; Szabolcsi, 2010) and Turkish (Tuğba Çolak, p.c.). On the other hand, we find cases where it does, such as Telugu (Balusu, 2005; Balusu and Jayaseelan, 2013) and Tlingit (Cable, 2014). All these cases are illustrated below. The import of these facts on Zimmermann’s generalization is unclear, since bound morphemes are not expected to be able to act as determiners. I mention them here for completeness and because the compositional analysis given below extends to them.

The facts discussed so far suggest the following requirements for a semantic analysis of distance-distributivity. First, the synonymy of the determiner, adnominal and adverbial uses of *each* in English should be captured, ideally by essentially identical lexical entries. Second, the fact that distance-distributive elements across languages share some part of their meanings (namely their individual-distributive readings) should be represented, as well as the fact that some of them can also have occasion readings. Third, the analysis should clarify the connections between distance-distributive elements and distributivity theory more generally, and the semantic variation across distance-distributive elements should be captured. Finally, an explanation for Zimmermann’s generalization should be readily available. The rest of the paper develops an analysis that fulfills these requirements.

3 Relating Overt and Covert Distributivity

The connection between Link’s D operator and *each* that was illustrated in (1) has been noted many times. I take adverbial *each* and related distance-distributive elements in Dutch, French, Italian, Japanese, Norwegian, and Russian to be D operators. These are the languages mentioned in Section 2 as being English-type. As for *jeweils* and its relatives in German-type languages like Bulgarian, Czech and Korean, we have seen that they can distribute over spatial and temporal intervals – arguably nonatomic entities. Link’s D operator always distributes down to individual atoms and can therefore not be extended to these cases. So I will connect them to Schwarzschild’s Part operator (Schwarzschild, 1996).

I now present a formally explicit, surface-compositional account of the overt distributive elements described in Section 2 in terms of the covert distributive operators D and Part discussed in the other paper and in the literature on covert distributivity (Link, 1987; Schwarzschild, 1996). For the sake of brevity, I will only execute the analysis for English *each* and German *jeweils*, but it should be clear how to extend

³⁴Szabolcsi (2010, p. 138, ex. 138)

³⁵Tuğba Çolak, p.c. to the author.

³⁶Tuğba Çolak, p.c. to the author. It may be that the sentence is acceptable under the reading *Can bought two sausages of each kind*.

³⁷Cable (2014, ex. 3b)

it to other distributive elements depending on which one of these two they pattern with. I will only show how to model the individual-distributive and the temporal occasion readings. The extension from the temporal to the spatial occasion reading is straightforward.

The guiding idea of the analysis is that overt distributive elements include two versions of the distributivity operator. *Each* includes the atomic distributivity operator *D* of Link (1987), which can only distribute over count domains. *Jewels* includes the cover-based distributivity operator *Part* of Schwarzschild (1996). I have argued in the other paper that this operator can also distribute over noncount domains like time. I adopt the strata-theoretic perspective from (Champollion, 2010). According to this theory, distributivity is a property with two parameters: dimension and granularity. I will suggest that *each* comes prespecified for “granularity=atom”. This blocks the setting “dimension=time”, so distributivity over occasions is unavailable. By contrast, *jewels* does not come prespecified for anything, so it can distribute over occasions.

Arriving at the meaning of *each* from the meaning of distributivity operators is somewhat of the reverse of the process by which Schwarzschild arrived at his *Part* operator, which “was based on a generalization of Dowty and Brodie’s (1984) account of floated quantifiers as verb phrase modifiers” (Schwarzschild, 1996, p. 137). Schwarzschild himself notes that the history of *Part* should not be taken for an endorsement that floated quantifiers are related to it, and argues that floated quantifiers should be distinguished from *Part* operators because he takes reciprocals to be licensed by *Part*, but not by adverbial *each*. He gives the following examples to support this claim.

- (51) a. They_j Part_i [saw each other_{j,i}].
b. *They_j each_i saw each other_{j,i}.

Whatever the merits of the particular analysis of reciprocals underlying example (51a), Schwarzschild’s argument is doubtful since many naturally-occurring examples analogous to his example (51b) can be found. The ones below are taken from the Corpus of Contemporary American English (Davies, 2008):

- (52) You each had each other and yet the teasing was relentless and he could be very naughty with you.
(53) One of the leaders is Rich Borow, Stephanie’s husband and nemesis on the bike; they each push each other hard.
(54) Communicate with other teachers, coaches, and paraprofessionals to see how you can each support each other.

I conclude that whatever fundamental differences there may be between overt and covert adverbial distributivity, the ability to license reciprocals is not one.

Before proceeding, let me specify a few background assumptions. Noun phrases are interpreted in situ, because I do not consider quantifier raising in this paper. Silent theta role heads, which denote thematic roles of type *ve* (event to individual), are located between noun phrases and verbal projections. The one that denotes the agent role can be either thought of as a silent case-marker-like part of the noun phrase, or as

little v or Voice, depending on whether it first combines with the subject noun phrase or with the verb phrase. The heads that denote the theme and recipient roles bear some conceptual similarity with applicative heads (Pylkkänen, 2008). I will occasionally omit or abbreviate these heads in my LFs but they should always be assumed to be there. The precise nature of the compositional process is not essential, but it affects the types of the lexical entries of distance-distributive elements so let me make it concrete. I assume that the following type shifters apply first to the theta role head, then to the noun phrase, and finally to the verbal projection. I will introduce a third type shifter in Section 6 below for the case where the theta role head combines first with the verbal projection and then with the noun phrase it belongs to.

- (55) a. Type shifter for indefinites: $\lambda\theta_{ve}\lambda P_{et}\lambda e.P(\theta(e))$
 b. Type shifter for definites: $\lambda\theta_{ve}\lambda x\lambda e.\theta(e) = x$

Each of these type shifters combines a noun phrase with its theta role head to build an event predicate of type $\langle vt \rangle$ which can combine with other predicates of the same type via intersection. For example, after the noun phrases *the boys* (definite) and *two monkeys* (indefinite) combine with the theta role heads $[ag]$ and $[th]$ respectively, their denotations are as follows.

- (56) $\llbracket [[ag] [the\ boys]] \rrbracket = \lambda e[*ag(e) = \bigoplus \text{boy}]$
 (57) $\llbracket [[th] [two\ monkeys]] \rrbracket = \lambda e[|*th(e)| = 2 \wedge *monkey(*th(e))]$

After the verb has combined with all its arguments, the event variable is existentially bound if the sentence is uttered out of the blue. If the sentence is understood as referring to a specific event, the event variable is instead resolved to that event. If the noun phrases combine directly with the verb, we get a scopeless reading as in (58). Here and below, I write $2M$ as a shorthand for $\lambda e[|*th(e)| = 2 \wedge *monkey(*th(e))]$.

- (58) $\llbracket [The\ boys\ saw\ two\ monkeys] \rrbracket = \exists e[*ag(e) = \bigoplus \text{boy} \wedge *see(e) \wedge 2M(e)]$

To generate distributive readings, we use Link's D operator, reformulated in the counterpart of this paper and repeated here as (59). As in the other paper, I assume that the D operator is coindexed with the thematic role of its target.

- (59) **Definition: Event-based D operator**
 $\llbracket D_\theta \rrbracket \stackrel{\text{def}}{=} \lambda V_{\langle vt \rangle} \lambda e[e \in * \lambda e'(V(e') \wedge \text{Atom}(\theta(e')))]$

As an example, the distributive reading of (58) is derived like this:

- (60) $\llbracket [[ag] [The\ boys] [D_{ag} [saw [[th] [two\ monkeys]]]] \rrbracket$
 $= \exists e[*ag(e) = \bigoplus \text{boy} \wedge e \in \llbracket [D_{ag}](\lambda e'[*see(e') \wedge 2M(e')]) \rrbracket]$
 $= \exists e[*ag(e) = \bigoplus \text{boy} \wedge e \in * \lambda e'[*see(e') \wedge 2M(e') \wedge \text{Atom}(ag(e'))]]$

This formula is true just in case there is an event e whose agent is the boys, and which consists of seeing-two-monkeys events whose agents are atomic. As discussed in the other paper, the background assumptions of algebraic semantics ensure that the seeing-two-monkeys events have boys as agents even though the formula does not

explicitly state this.

Here are the entries for adverbial, adnominal, and determiner *each*. An explanation follows below. An illustration of the derivation of a basic sentence like *The boys saw two monkeys each* is shown in Figure 1.

$$(61) \quad \llbracket \text{each}_\theta \rrbracket_{\text{adverbial}} = \llbracket D_\theta \rrbracket = (59)$$

$$(62) \quad \llbracket \text{each}_\theta \rrbracket_{\text{adnominal}} = \lambda P_{et} \lambda \Theta_{ve} \lambda e. e \in \llbracket D_\theta \rrbracket (\lambda e'. P(\Theta(e')))$$

$$(63) \quad \llbracket \text{each} \rrbracket_{\text{determiner}} = \lambda P_{et} \lambda \theta_{ve} \lambda V_{vt} \lambda e [\theta(e) = \bigoplus P \wedge \llbracket D_\theta \rrbracket (V)(e)]$$

I assume that adverbial *each*, as shown in (61), is a verb phrase modifier just like the D operator, and can therefore be given the same entry as that operator. I adopt for concreteness the assumption that adverbial *each* is an adverb adjoined to VP. This is similar what has been argued for floating quantifiers in general by Dowty and Brodie (1984), Bobaljik (1995) and Doetjes (1997). For another view that analyzes floating quantifiers as the remaining part of a noun phrase the rest of which has moved away from it, see for example Safir and Stowell (1988) and Sportiche (1988). The latter view makes a formal link between *each* and its antecedent available for independent reasons since there is a movement relation between them, while the former requires me to assume that the two are coindexed. Therefore the latter view, which I do not adopt here, would be likely to be at least as compatible with my approach than the former view.

Adnominal and determiner *each*, as shown in (61) and (62), need to be type-shifted, but both are defined in terms of the D operator. This captures the fact that they are essentially synonymous. As shown in (62), adnominal *each* carries an index. I assume that it is coindexed with the theta role θ of its antecedent. It first combines with its host predicate P (e.g. *two monkeys*), and then with the theta head Θ of the host (which is not to be confused with the theta role of its antecedent). Afterwards, it combines intersectively with the verbal projection to which its host attaches (e.g. the verb *see*). This means that adnominal *each* does not take scope over the verbal projection but only over its own complement (Dotlačil, 2012). By contrast, adverbial *each* takes scope over the verbal projection. In this, I follow LaTerza (2014b), who provides evidence the following minimal pair as evidence for this contrast:

- (64) a. John and Bill served [four meals each] to (exactly) three judges.
b. John and Bill each served four meals to (exactly) three judges.

As LaTerza reports, speakers judge (64a) true of situations where there are at most three judges, while (64b) is true in situations which allow up to six different judges. This is predicted by giving adnominal and adverbial *each* different scopes, as he notes. For example, sentence (64b) can be derived as in Figure 2.

My entry for adnominal *each* combines with its host in two steps, in order to give it access to both the predicate and the theta head. This is not essential, but it allows us to ensure that the type of the predicate is $\langle e, t \rangle$, which provides a partial account of the “counting quantifier requirement” that prevents such phrases as **most men each* (Safir and Stowell, 1988; Sutton, 1993; Szabolcsi, 2010, §10.5). This is not enough to provide a complete account since it will not rule out bare plurals as in **They saw monkeys each*,

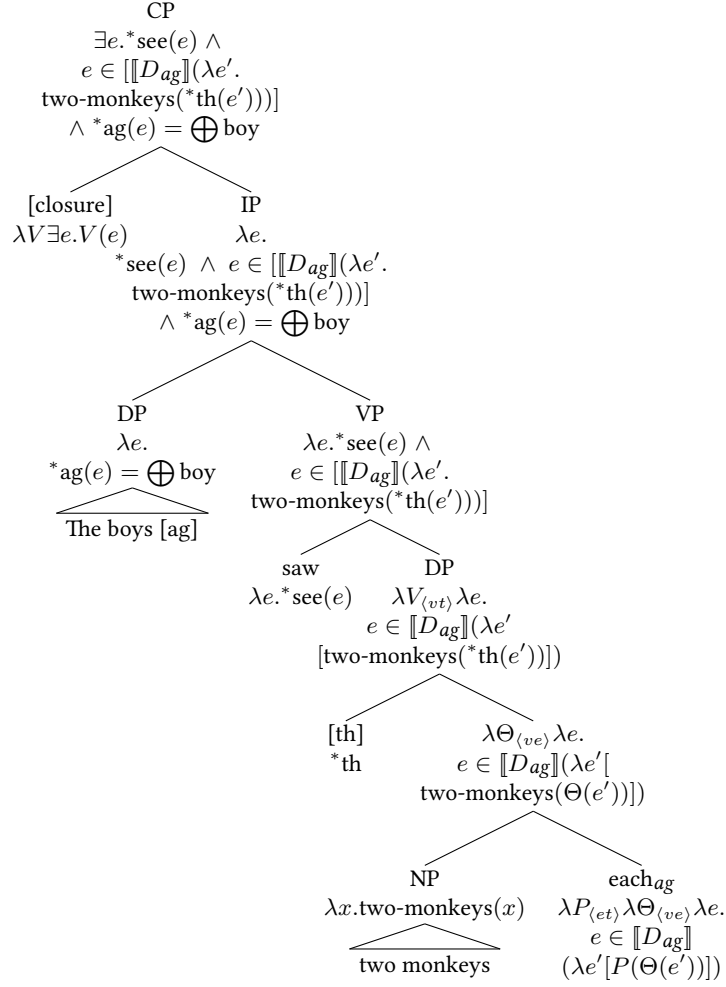

Figure 1: Deriving *The boys saw two monkeys each*.

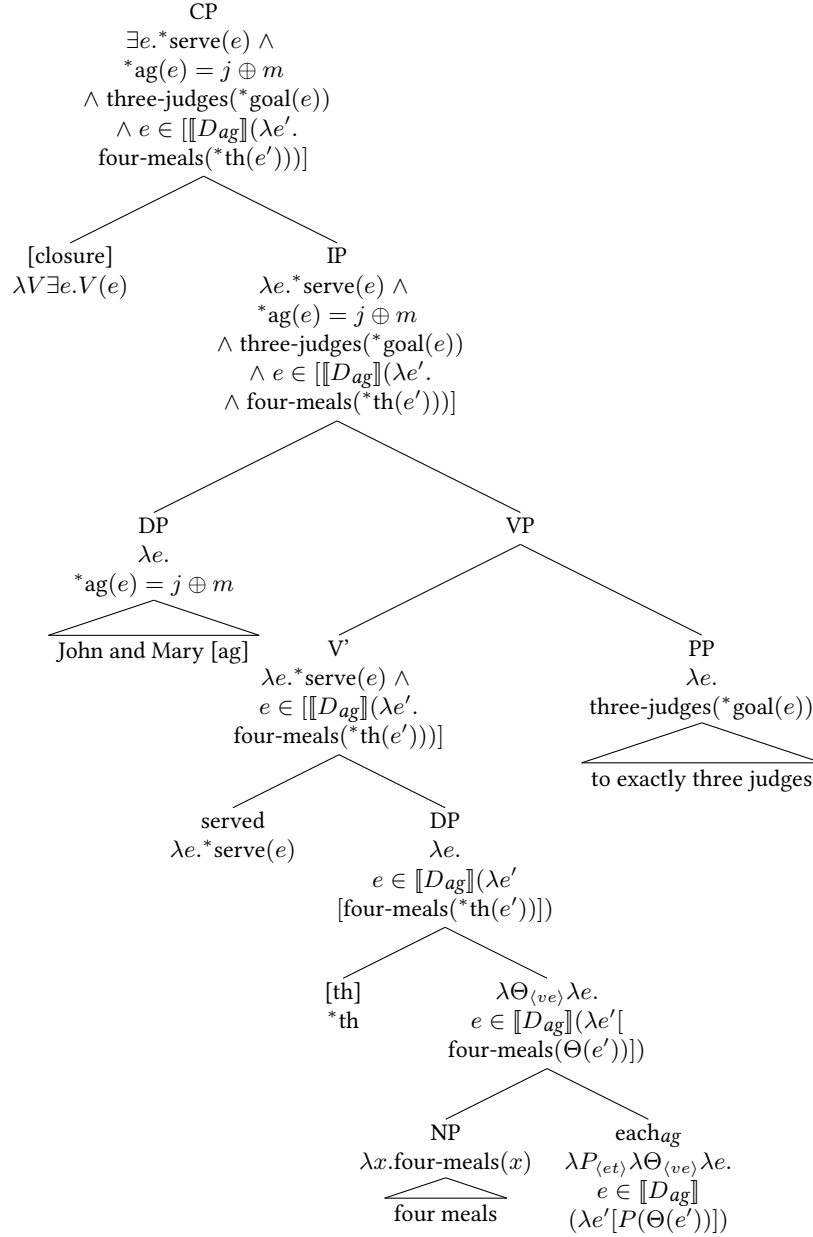

Figure 2: Deriving *John and Mary served four meals each to exactly three judges*.

as pointed out in Cable (2014). If no independent account of these kinds of mismatches can be provided, then it may not be necessary to place *each* between the host predicate and the theta head after all. The choice is immaterial for the rest of this paper.

Determiner *each*, as shown in (63) is not coindexed with anything because it is not a distance-distributive element. It combines first with a nominal and then with a theta head. The result is a phrase of VP modifier type $\langle vt, vt \rangle$, which is also the type of D_θ . Some intermediate steps of the derivations of (5) are shown in (65) and (66).

- (65)
$$\begin{aligned} & \llbracket [\text{two monkeys}] \text{ each}_{ag} [\text{th}] \rrbracket \\ &= \lambda e [\llbracket D_{ag} \rrbracket (\lambda e' [|*th(e')| = 2 \wedge *monkey(*th(e'))]) (e)] \\ &= \lambda e [e \in * \lambda e' [*see(e') \wedge |*th(e')| = 2 \wedge *monkey(*th(e')) \wedge \text{Atom}(ag(e'))]] \end{aligned}$$
- (66)
$$\begin{aligned} & \llbracket [\text{Each boy}] [ag] \rrbracket \\ &= \lambda V_{vt} \lambda e [*ag(e) = \bigoplus \text{boy} \wedge \llbracket D_{ag} \rrbracket (V)(e)] \\ &= \lambda V_{vt} \lambda e [*ag(e) = \bigoplus \text{boy} \wedge e \in * \lambda e' [V(e') \wedge \text{Atom}(ag(e'))]] \end{aligned}$$

My reformulation of the Part operator in the other paper, repeated here as (67), is also the lexical entry of adverbial *jewels*, as shown in (68). The same type shift as in (62) brings us from (68) to adnominal *jewels*, as shown in (69).

- (67) **Definition: Event-based Part operator**

$$\llbracket \text{Part}_{\theta, C} \rrbracket \stackrel{\text{def}}{=} \lambda P_{\langle vt \rangle} \lambda e [e \in * \lambda e' (P(e') \wedge C(\theta(e')))]$$
(Takes an event predicate P and returns a predicate that holds of any event e which consists entirely of events that are in P and whose θ s satisfy the contextually salient ‘cover predicate’ C .)
- (68)
$$\llbracket \text{jewels}_{\theta, C} \rrbracket_{\text{adverbial}} = \llbracket \text{Part}_{\theta, C} \rrbracket = (67)$$
- (69)
$$\llbracket \text{jewels}_{\theta, C} \rrbracket_{\text{adnominal}} = \lambda P \lambda \Theta \lambda e [\llbracket \text{Part}_{\theta, C} \rrbracket (\lambda e' [P(\Theta(e'))]) (e)]$$

As in the case of the Part operator, the granularity parameter C of *jewels* can be set to *Atom* so long as its dimension parameter θ is set to a function into a count domain, such as *ag*. In that case, *jewels* distributes over individuals and is equivalent to *each*. The following example illustrates this with sentence (6a); sentence (6b) is equivalent.

- (70) Die Jungen haben jewels_{ag, Atom} zwei Affen gesehen.
The boys have DIST two monkeys seen.
“The boys have each seen two monkeys.”

If – and only if – there is a supporting context, the anaphoric predicate C can be set to a salient antecedent other than *Atom*, and in that case θ is free to adopt values such as τ (runtime). This leads to occasion readings. Suppose for example that it is in the common ground that the boys have been to the zoo to see animals last Monday, last Wednesday and last Friday, and that (6a) is uttered with reference to that state of affairs, or sum event. It is interpreted as follows.

- (71)
$$\begin{aligned} & \llbracket \text{Die Jungen haben jewels}_{\tau, \text{zoovisit}} \text{ zwei Affen gesehen.} \rrbracket = \\ & *ag(e_0) = \bigoplus \text{boy} \wedge *see(e') \wedge e_0 \in * \lambda e' [|*th(e')| = 2 \wedge *monkey(*th(e')) \wedge \\ & \text{zoovisit}(\tau(e'))] \\ & \text{“The boys have seen two monkeys on each occasion.”} \end{aligned}$$

Since the sentence refers specifically to the sum e_0 of the three events in question, the event variable in (71) is resolved to e_0 rather than being existentially bound. The predicate that is true of any time interval at which a zoo visit takes place, call it *zoovisit*, is also salient in this context. So C can be resolved to *zoovisit* rather than to *Atom*. Since there are no atoms in time, it is only now that θ can be set to τ , rather than to ag as in (70). What (71) asserts is that e_0 has the boys as its agents; that it can be divided into subevents, each of whose runtimes is the time of a zoo visit; and that each of these subevents is an event whose theme are two monkeys. That these subevents are seeing events is entailed by the fact that *see* is lexically distributive on its theme argument, which in turn is formally represented as a meaning postulate, as discussed in the other paper. I assume that runtime is closed under sum just like other thematic roles ($\tau = *\tau$), or in other words, it is a sum homomorphism. This means that any way of dividing e_0 must result in parts whose runtimes sum up to $\tau(e_0)$. Assuming that $\tau(e_0)$ is the (discontinuous) sum of the times of the three zoo visits in question, this entails that each of these zoo visits is the runtime of one of the seeing-two-monkeys events. This is the occasion reading.

4 Zimmermann's Generalization Explained

This section discusses the question how to capture the correlation expressed in Zimmermann's generalization (13). That is to say, why does a distance-distributive element which can also be used as a distributive determiner lack the occasion reading? Zimmermann himself proposes a syntactic explanation: Determiners must agree with their complement; adnominal or adverbial *each* also has a complement, a proform that must acquire its agreement features from its antecedent, which is the antecedent of *each*; only overt antecedents have agreement features; so adnominal/adverbial *each* cannot have a covert antecedent; so it cannot refer to a contextually supplied but not overtly mentioned antecedent such as a salient set of occasions.

This explanation makes the right predictions given the assumption that covert antecedents cannot have agreement features, and it is compatible with the present framework. However, this assumption is problematic. To mention a simple example, German has grammatical gender, so for example, the gender of *Tisch* 'table' is feminine. Knowing this, I can point to a table and say with reference to it:

- (72) Den hab ich gebraucht gekauft.
 This.m have I used bought.
 'I have bought this used.'

But I cannot point to it and say:

- (73) *Die hab ich gebraucht gekauft.
 'This.f. have I used bought.'

As this example shows, a deictic pronoun in German has to agree in grammatical gender with its antecedents (that is, with the gender of the noun phrase that would most aptly describe this antecedent) even though the antecedent has not been mentioned

explicitly.

A similar phenomenon was pointed in English by Tasmowski-De Ryck and Verluyten (1982). English pronouns agree with their antecedents based on syntactic rather than semantic grounds, as is exemplified by *pluralia tantum* such as *pants* and *scissors* which are syntactically plural but semantically singular. Pronouns show syntactic agreement with their antecedents even when these antecedents are not overtly mentioned:

- (74) a. (John wants his pants that are on a chair and he says to Mary:)
Could you hand them/*it to me, please?
b. (Same situation but with a shirt:)
Could you hand *them/it to me, please?

For a recent discussion of these facts, and an explanation in terms of covert syntactic antecedents that c-command the entire sentence in question, see Collins and Postal (2012, ch. 4).

Zimmermann's analysis assumes that *each* indeed has a silent complement and that the two agree. Since *each* does not show overt agreement in English, it is difficult to tell whether it in fact agrees with anything, just like English *all*. In general, adverbial distance-distributive elements do not have to agree with their antecedents. For example, German *all*- 'all' and *jed*- 'every, each' can both be used as determiners, as seen in (75) and (76), and as adverbial distance-distributive elements, as seen in (77) and (78). When used as determiners in count domains, the former is plural and requires plural agreement, and the latter is singular and requires singular agreement, just like their English counterparts. When used as adverbials, *alle* is plural, as shown in (77) but *jed*- must be singular, as shown in (78). The latter is the case even when the antecedent of *jed*- is plural.

- (75) Alle Jungen haben geniest.
All.pl boy.pl have.pl sneezed.
'All the boys have sneezed.'
- (76) Jeder Junge hat geniest.
Each.sg boy.sg has.sg sneezed.
'Each boy has sneezed.'
- (77) Die Jungen haben alle/*aller geniest.
The.pl boy.pl have.pl all.pl/all.sg. sneezed.
'The boys have all sneezed.'
- (78) Die Jungen haben jeder/*jede geniest.
The.pl boy.pl have.pl each.sg/each.pl sneezed.
'The boys have each sneezed.'

This shows that at least some distance-distributive elements do not need to agree with their antecedents. To put it differently, on Zimmermann's assumptions, the proform associated with *jeder* in (78) is singular and so it cannot have acquired its agreement features from its antecedent *Jungen*, since that antecedent is plural.

While Zimmermann's account seems problematic, its difficulties can perhaps be overcome, and it is by itself not incompatible with the present framework. But in the

context of the general theory adopted here, a more straightforward explanation suggests itself. Distributive determiners like English *each* are only compatible with count nominals. We know this since, for example, **each mud* is ungrammatical. Formally, this amounts to an atomicity requirement of the kind the Link’s D operator provides. This requirement can be seen as independent evidence of the atomic distributivity hard-coded in the entry (63) via the D operator. In other words, the distance-distributive element inherits the atomicity requirement of the determiner. This explanation is in line with the notion of parameter settings imported from strata theory and described above. That is, in English, adnominal, adverbial and *each* have identical meanings up to type-shifting. Determiner *each* is only compatible with count domains because its granularity parameter is hardwired to the value “Atom”. Adnominal *each* is formally identical to determiner *each*, so it inherits this property.

5 Previous Work: Zimmermann (2002b)

This section discusses the semantic account of *jewels* and *each* offered in Zimmermann (2002b). There are useful summarizations of the essence of Zimmermann’s proposal in a number of places (Zimmermann, 2002a; Blaheta, 2003; Dotlačil, 2012). Zimmermann takes adnominal *each* and *jewels* to be prepositional phrases that are only partially pronounced, but this aspect does not really influence the semantic composition. The meaning of *each*, or more precisely of the prepositional phrase that is supposed to contain it, is as follows (Zimmermann, 2002b, p. 210). While the relevant discussion is actually about adnominal *jewels*, it carries over to adnominal *each* without changes, so I present it in terms of *each* for clarity.

$$(79) \quad \llbracket \text{each} \rrbracket (\text{Zimmermann}) = \lambda P. \forall z [z \in Z_i \rightarrow \exists x [P(x) \wedge {}^*R_j(z, x)]]$$

This meaning is a property of predicates that holds of a given predicate P iff every member of a certain plurality Z_i stands in the algebraic closure *R_j of a certain relation R_j to some entity of which P holds. In this definition, Z_i and R_j are free variables that are assumed to be coindexed, respectively, with the antecedent of *each* and with the relation that is denoted typically by the verb. Take for example sentence (10), repeated here as (80) with the coindexation added. Here P is the denotation of *two monkeys*, Z is coindexed with *the boys*, and R is coindexed with *saw*.

$$(80) \quad [\text{The boys}]_i [\text{saw}]_j \text{ two monkeys each}_{i,j}.$$

Here is how this sentence would be represented by Zimmermann (2002b). First, the entry for *each* is applied to *two monkeys*, which is taken to denote a predicate of sum individuals that I will represent here by the shorthand *two-monkeys*. This results in an open proposition with two free variables:

$$(81) \quad \llbracket \text{two monkeys each}_{i,j} \rrbracket = \forall z [z \in Z_i \rightarrow \exists x [\text{two-monkeys}(x) \wedge {}^*R_j(z, x)]]$$

The next steps involve lambda-abstraction over the free variables, via a rule that Zimmermann calls “index-triggered lambda abstraction”, a variant of a rule which is taken to apply when a type mismatch makes function application impossible Bittner

(1994, p. 69).

(82) **Index-triggered λ -abstraction (Zimmermann, 2002b, p. 217):**

If the semantic types of a proposition-denoting expression α and its syntactic sister β do not match, and if $\llbracket \alpha \rrbracket$ contains a free variable u_i that shares an index ‘i’ with β , λ -abstraction in $\llbracket \alpha \rrbracket$ over index ‘i’ is licensed, and $\lambda u_i. \llbracket \alpha \rrbracket$ is a value for α .

This rule allows a constituent with a free variable in it to combine with another constituent that is coindexed with that variable. For example, in (80), the constituent *two monkeys each_{i,j}* has the free variable j in it, which carries the same index as the constituent *saw_j*. Since the two constituents are sisters, index-triggered λ -abstraction applies, with the result as shown in (83), as discussed in (Zimmermann, 2002b, p. 226).

$$(83) \quad \lambda R. \forall z [z \in Z_i \rightarrow \exists x [\text{two-monkeys}(x) \wedge *R_j(z, x)]]$$

Zimmermann takes the classical Davidsonian view on verb meaning, under which n -ary verbs denote $n + 1$ -ary relations between arguments and events, and he assumes that the event argument can be saturated at VP level by existential closure so that the verb *saw* can have the right type to combine with (83), as shown below:

$$(84) \quad \llbracket \text{saw}_j \rrbracket = \lambda y \lambda x. \exists e [\text{see}(x, y, e)]$$

$$(85) \quad \llbracket (83) \rrbracket (\llbracket (84) \rrbracket) = \forall z [z \in Z_i \rightarrow \exists x [\text{two-monkeys}(x) \wedge \exists e [* \text{see}(z, x, e)]]]$$

In the derivation, the existential quantifier over events ends up outside the scope of the star operator. This is a bit mysterious if the star operator is introduced as a part of the meaning of *each*, but the problem would disappear if the star operator, or something to its effect such as lexical cumulativity was introduced as part of the meaning of the VP or through background assumptions. In any case, the result of the computation, as shown in (85), is another open proposition. The last step is to combine this with the antecedent, *the boys_i*, in another instance of index-triggered λ -abstraction. The result is as follows:

$$(86) \quad \forall z [(z \in \bigoplus \text{boy}) \rightarrow \exists x [\text{two-monkeys}(x) \wedge \exists e [* \text{see}(z, x, e)]]]$$

Zimmermann’s system works as long as there are constituents that express the relation R and the sum Z that figure in the meaning of *each*. In the case of the sum, this is not a problem, since the antecedent of *each* is always a constituent. In the case of the relation, however, it is not always guaranteed that such a constituent exists (Dotlačil, 2011):

- (87) a. Alex and Sasha visited the capitals of three states each. (Blaheta, 2003)
b. Alex and Sasha dragged three bags through four puddles each. (Blaheta, 2003)
c. Two women got the prize money and a silver medal each. (Boeckx and Hornstein, 2005)

Here the relation with which R in (79) would have to be coindexed is expressed by several words that do not form a constituent: “visited the capitals of”, “dragged three

bags through”, “got the prize money and”. Zimmermann’s account is not flexible enough to achieve this. The solution is to give binominal *each* scope only over its noun phrase (Dotlačil, 2011). This has been adopted here in the entry (62).

The prediction of this solution is that binominal *each* should occur in sentences where its antecedent stands in a cumulative-quantification relation with another noun phrase. This prediction seems borne out for some speakers. To see this, consider the following example as a description of an election in which every voter has exactly one vote, and there are two candidates to choose from:

(88) 100 million voters gave two candidates one vote each.

Many of the speakers I consulted only interpret this sentence as describing situations in which there are two votes per candidate, either in the sense that each voter cast two votes or in the sense that the 100 million voters cooperated to cast a total of only two votes. However, I did find speakers who can take the sentence to describe a situation in which every one of the 100 million voters voted for only one of the candidates, with some of these votes going to the first candidates and the rest going to the second. It is this reading that involves a cumulative relation between *two candidates* and *one vote each*. To see this, observe that *one vote each* has the same extension as *100 million votes* in the scenario described. Each of the 100 million votes went to one of the two candidates, and each of the two candidates got some of the 100 million votes. This is the hallmark of cumulative quantification (Scha, 1981; Krifka, 1999).

Here is another example that makes the same point perhaps more vividly. Imagine there are twenty boys and ten girls in a room and suppose that the following happens.

(89) Twenty boys gave ten girls one kiss each.

How many kisses were given in total? If twenty is a possible answer, as some of my consultants agree, and if each boy gave one girl a kiss and each girl was kissed by at least one of the boys, then the sentence has a cumulative reading and *each* take *twenty boys* as its antecedent. (Another possible answer is two hundred. In this case, arguably, *each* takes *ten girls* as its antecedent, and the entire vP *gave ten girls one kiss each* is in the scope of a D operator that distributes it over the twenty boys.)

The fact that cumulative quantification is possible between the host phrase of *each* and a noun phrase that is not its antecedent means that the universal quantifier or distributive operator that is contributed by *each* must not be given scope over the entire relation that holds between each member of the antecedent and each member of the host denotation. In Zimmermann’s implementation, this is the relation *R*. As can be seen in (79), the universal quantifier introduced by *each* in Zimmermann’s implementation actually takes scope over *R*. For this reason I see no way to represent this kind of cumulative quantification in Zimmermann’s system. On my account, this is straightforward. The key is that adnominal *each* does not take scope over the verbal predicate, just over the host noun phrase, as shown in the entry in (62). The result of analyzing (88) is as follows:

(90) $\exists e.[*give(e)$
 $\wedge 120\text{-million-voters}(*ag(e))$

$$\begin{aligned} &\wedge \text{two-candidates}(*\text{ben}(e)) \\ &\wedge e \in * \lambda e' [\text{vote}(*\text{th}(e')) \\ &\wedge \text{Atom}(\text{ag}(e'))]] \end{aligned}$$

This representation states that there is a sum of giving events whose agents sum up to 100 million voters, whose beneficiaries sum up to two candidates, and which consist of subevents with atomic agents and individual votes as themes. The background assumptions of algebraic semantics ensure that this entails that there were 100 million such subevents.

Figure 3 shows the compositional interpretation of (88). Since the current consensus in syntax is that the syntax of ditransitives differs somewhat from their surface structure, I have chosen to make this analysis harmonize with the syntax proposed in Marantz (1993) and recently defended by Bruening (2010). For this purpose, I have assumed that the *Voice* and *Appl* heads introduce the thematic roles *ag* and *ben* respectively, and I have type-shifted these heads accordingly. For reasons of clarity, I show the meanings of these heads only in their type-shifted form, but really they should be thought of as having the same meanings as above, that is, **ag* and **ben*. The type-shifter I have used here is the following:

$$(91) \quad \lambda \theta_{ve} \lambda V_{vt} \lambda P_{et} \lambda e. V(e) \wedge P(*\theta(e))$$

An equivalent alternative, if one does not mind introducing additional compositional operations, would be to use the event identification operation from Kratzer (1996). For details on how this works, see Harley (2012).

6 *Each* as a PP Modifier

This section discusses the compositional interpretation of English *each* when it occurs as the modifier of a prepositional phrase. Two examples in which this is the case are the following:

- (92) Mary put the books each back on the bookshelf. (Maling, 1976)
- (93) 300 quilt patches covered two workbenches each with two bedspreads (Schein, 1993).

Distance distributive *each* in sentences like (93) plays a role in an argument for Neo-Davidsonian event semantics and thematic roles offered by Schein (1993). I discuss this argument in Champollion (2009). Here, I take Neo-Davidsonian event semantics for granted and I focus on giving a compositional implementation, which Schein himself does not provide.

The word *each* appears to occupy the same syntactic position in these sentences as the word *all* in the following:

- (94) He read the books both to someone famous. (Janke and Neeleman, 2012)

While not all speakers accept such sentences, there is some indication that distance-distributive and other floated elements can modify prepositional phrases that follow

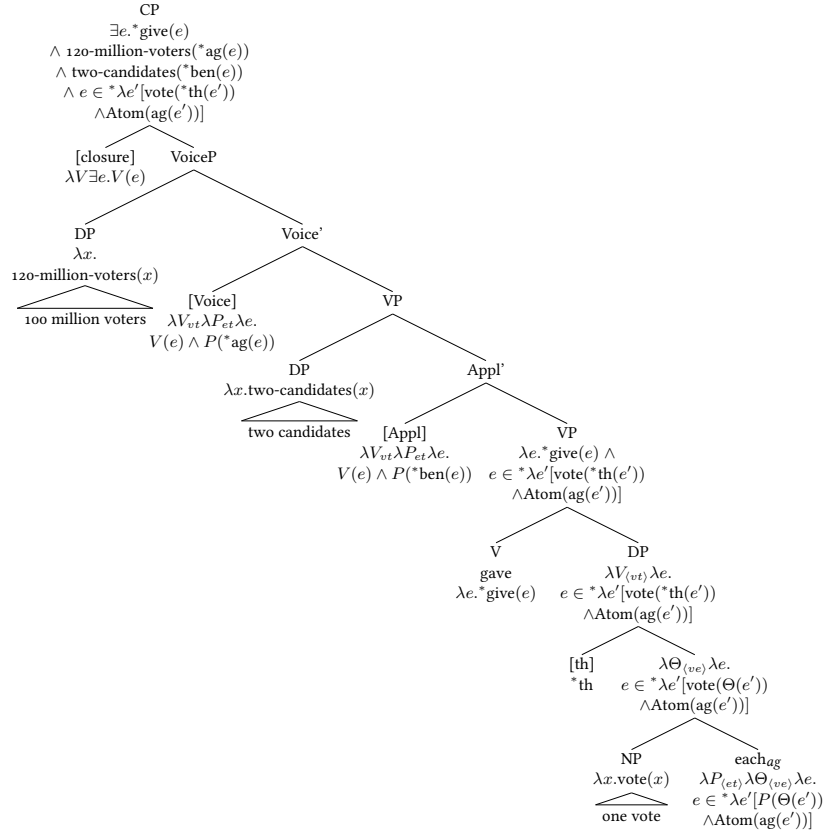

Figure 3: Deriving *100 million voters gave two candidates one vote each*.

them, as shown by the fronting test. The examples in (95) are from Bobaljik (1995, p. 214) and the one in (96) is due to Benjamin Bruening (p.c.).

- (95) a. The magicians disappeared all at the same time.
 b. All at the same time, the magicians began to appear.
 c. *At the same time, the magicians began to appear all.
- (96) All back at the farm, the boys sat down to lunch.

Aside from the parallel with *all*, two facts suggest that in sentences like (92), the word *each* does not modify the noun phrase to its left but the prepositional phrases to its right. First, definite noun phrases like *the books* cannot normally be modified by adnominal *each*. Second, (93) can be read with a prosodic break between *two workbenches* and *each* and in that case it has a reading where there is a total of two workbenches and a total of four bedspreads. This is the reading that Schein intends it to have, as evidenced by the scenario description he offers:

“The tailor has taken 300 quilt patches from his stock to fabricate four bedspreads, which now cover over the workbenches. It cannot be assumed that any of the patches of irregular shape and size was sewn into any one bedspread. The tailor may have divided it among several. It may furthermore be the case that no group of fewer than the 300 quilt patches cover any workbench. All that can be said is that there was an event of two workbenches each being covered over with two bedspreads, and *there* 300 quilt patches made up the covers. The cross-reference to events is essential.” (Schein, 1993, p. 9)

The word *each* in sentence (93) could also be read as an adnominal modifier that modifies *two workbenches*. In that case, the sentence requires there to be more than two workbenches, while Schein’s scenario description suggests that there are only two workbenches in total. The use of *each* here, and in sentences (92) and (94), can be called adverbial or perhaps “ad-prepositional”, depending on what syntactic structure one assumes: a right-branching structure like [V [DP PP]] or a left-branching structure like [[V DP] PP]. Both structures have been advocated in the literature. For a recent overview, see for example Janke and Neeleman (2012). On some incarnations of the right-branching analysis, *each* can modify the trace of a verb including the one advocated for sentence (94) by (e.g. Janke and Neeleman, 2012). For example, Janke and Neeleman take *read* in (94) is taken to originate between *both* and *to* and to move leftward. On the left-branching analysis, the most natural option is to regard these elements as “ad-prepositional” modifiers of a prepositional phrase, like the adverb *back* in *back at the farm*. I will take this choice here.

The following formula captures this reading:

- (97) $\exists e. *cover(e)$
 $\wedge *quilt-patch(*ag(e)) \wedge |*ag(e)| = 300$
 $\wedge *workbench(*th(e)) \wedge |*th(e)| = 2$
 $\wedge e \in *\lambda e' [*bedspread(*instr(e')) \wedge |*instr(e')| = 2 \wedge Atom(th(e'))]$

Formula (97) is derived as in Figure 4, where I have used shortcuts like *300-quilt-patches* for better readability. It can be paraphrased as follows: There is a sum of covering events whose agents sum up to 300 quilt patches, whose themes sum up to two workbenches, and which can be divided into two smaller sum events, each of which involves two bedspreads and one of the workbenches. All this is true in the scenario Schein describes. The cross-reference to events, as Schein calls it, is achieved by having predicate denoted by the subject noun phrase *three hundred quilt patches* modify the same event variable as the PP *each with two bedspreads*.

7 Summary and Discussion

At the end of Section 2, I had suggested that the facts reviewed in that section suggest the following requirements for a theory of distributivity. First, the synonymy of the determiner, adnominal and adverbial uses of *each* in English should be captured, ideally by essentially identical lexical entries. Second, the fact that distance-distributive elements across languages share some part of their meanings (namely their individual-distributive readings) should be represented, as well as the fact that some of them can also have occasion readings. Third, the analysis should clarify the connections between distance-distributive elements and distributivity theory more generally, and the semantic variation across distance-distributive elements should be captured. Finally, an explanation should be readily available for the crosslinguistic observation that distance-distributive elements that can also be used as determiners can only distribute over individuals (Zimmermann’s generalization).

Let me briefly summarize how the theory presented in this paper addresses these issues. The synonymy of the determiner, adnominal and adverbial uses of *each* in English is captured by the fact that they are all derived from Link’s D operator. I have represented the fact that distance-distributive elements across languages share some part of their meanings by deriving them from related distributivity operators (Link’s or Schwarzschild’s) which differ from each other only in their parameter settings. On the theory presented here, distance-distributive items display the same parametric variation as covert distributivity operators do, not only insofar as nonatomic distributivity is concerned, but also insofar as the ability is concerned to target different thematic roles or time. The semantic variation among distance-distributive elements is captured by restriction on parameter settings. One type of element, exemplified by English *each*, is hard-wired for distribution over atoms and the other one, exemplified by German *jeweils* also allows distribution over nonatomic contexts. Zimmermann’s generalization is explained by the natural assumption that distance-distributive elements are formally identical to distributive determiners and therefore inherit their inability to distribute over nonatomic domains, no matter if these domains are mass or temporal.

Taken together, this paper and its counterpart suggest the following general picture of distributivity. No matter whether distributivity is introduced by an overt or by a covert element, it always involves a certain domain that contains the individuals or the material to be distributed over, and a certain size or granularity that specifies how finely the relevant predicates are distributed. When the domain question is a count domain, for example when we distribute over people or objects, then it is always

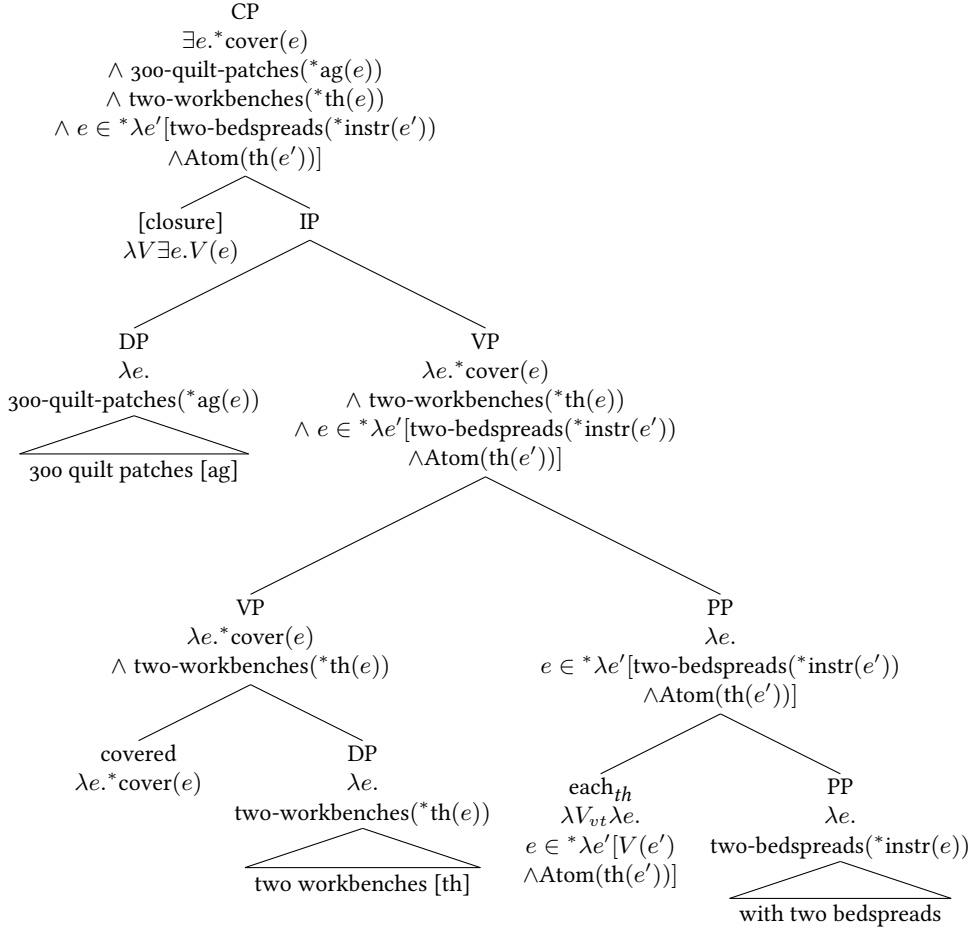

Figure 4: Deriving *300 quilt patches covered two workbenches, each with two bedspreads*.

possible to distribute over these objects one by one. When the domain in question does not make such atomic units available, as in the case of time or space, two things can happen. Either the element in question does not allow distribution over such nonatomic domains, for example because it is incompatible with non count domains to begin with, or else it looks for a salient cover or set in the context, such as a salient set of temporal locations. Those distributive elements that can do this in principle can also do this in count domains even though atoms are available.
