

A Two-Tiered Theory of Control

Idan Landau

Abstract

There is a persistent intuition running from the earliest to the most recent works on the topic, that obligatory control (OC) complements fall into two distinct types. In this study I recast this intuition in terms of the semantic distinction between attitude and non-attitude complements. I argue that the latter establish control by simple predication ("predicative control") but the former establish it by variable binding, where the bound variable is a projected coordinate of the embedded context of evaluation ("logophoric control"). I offer an explicit syntax-semantics analysis of the two types, utilizing the idea that logophoric control structures are constructed as a second tier above predicative control structures. In both, PRO figures as a minimal, featureless pronoun, which functions as a λ -abstractor upon movement.

The analysis derives the obligatory *de se* reading of OC PRO as a *constructional* property of attitude complements without ascribing any inherent feature to PRO (a minimal pronoun). It fares better than the prominent semantic alternatives – the property theory and the indexical shift theory of OC – in various respects, theoretical and typological. Importantly, it is capable of deriving a striking universal asymmetry between OC in attitude and non-attitude contexts: the fact that agreement on the embedded verb blocks the former but not the latter. This is handled by reference to the differential agreement properties of predication and variable binding. Further contrasts between the two types of OC follow, some of which unnoticed before, such as the visibility of implicit controllers and the [\pm human] value of PRO.

1. Introduction

There is a curious schism in the generative scholarship of control, going back to the early 1970s, between the work done in syntax and typology and the work done in formal semantics. While a great deal has been discovered about the nature of control within these two research strands, very few attempts have been made to compare and correlate their results within a broader theory that encompasses all the major facets of control. An attempt to formulate such a theory is presented in this study. At the same time, the theory to be developed revives and reinterprets a very persistent intuition running through much of the classical work: That the unitary appearance of Obligatory Control (OC) into complements conceals an underlying *duality* of structure and mechanism.

Concretely, I will propose that OC is achieved either through *predicative* control or through *logophoric* control. Empirically, the latter applies in attitude complements, the former in nonattitude complements. In predicative control, the complement is a property-denoting projection, while in logophoric control, it is a propositional projection constructed as a second tier above the predicative complement; hence the term “a two-tiered theory of control” (TTC). Furthermore, while predicative complements establish OC via simple predication, logophoric complements establish OC via variable binding, the bound variable being a projected coordinate of the embedded context of evaluation. Crucially, in both types the element known as PRO functions as property-creating abstractor.

The characteristic *de se* reading in logophoric control arises, in this analysis, as a special case of *de re* ascription, induced by the OC complementizer, and *not* by local operator binding or indexical shift, the more common devices in previous studies. The argument rests on the premise that only this analysis involves direct variable binding by the controller, and variable binding in OC plays a key role in explaining a fundamental asymmetry in the crosslinguistic distribution of predicative vs. logophoric complements. Thus, we present a striking case of syntactic typology *choosing* among semantically equivalent analyses (of obligatory *de se* in OC). We also show that other syntactic and semantic properties differentiate the two types of control, bolstering the two-tiered theory on independent grounds.

As already mentioned, the duality of OC is an old idea, and it is useful to set the stage by taking a quick look at the considerations that lay behind it.¹ The first generative study of control, Rosenbaum 1967, already distinguished between complements where the nonfinite VP is only dominated by S (VP-complements) and those where it is dominated by NP/PP over S (NP/PP-complements); the distinction had to do with the absence or presence of “nominal” behavior under passive or pseudocleft formation.² Interestingly, Rosenbaum

¹ Another idea with a long history is that non-complement clauses fall under different type of control – commonly called Non-Obligatory control (NOC). These two ideas are distinct, even if their genealogies are confusingly entangled (see Landau 2000 for the relevant demarcation). Except for some comments in the conclusion, I will have nothing to say about NOC in this study.

² For empirical problems with this distinction, see Bowers 1968, Wagner 1968 and Stockwell, Schachter and Hall Partee 1973:511-527.

was only interested in formulating the Equi-NP Deletion rule (which deleted the controllee under coreference with the controller), skirting the fundamental question of *why* coreference is obligatory in some cases and merely optional in others.

This latter question became the key criterion for later studies that highlighted the dual nature of OC. Focusing on English, the question was how to distinguish structures where an OC complement alternates with a *for*-infinitive with a lexical subject from structures where OC is the only option.

- | | | | |
|-----|----|--|---------------------|
| (1) | a. | Bill _i agreed PRO _{i/*j} / for Mary to join the club. | <i>OC or for-NP</i> |
| | b. | Bill _i condescended PRO _{i/*j} / *for Mary to join the club. | <i>Only OC</i> |

For Chomsky and Lasnik 1977, "control" in structures of type (1a) involved the deletion of a reflexive pronoun (*Refl*-deletion, or in short, Equi) whereas structures of type (1b) involved obligatory control of PRO, a wholly distinct derivation. The distinction itself, however, was encoded as a lexical feature and was left unexplained.

The same empirical cut was taken in Williams 1980 to reveal the contrast between optional coindexing and predication. For Williams, the former was a species of NOC, so that cases like (1a) were put in the same basket as cases like *John_i agreed that [PRO_i/Mary joining the club] would be a step forward*. This was a terminological pitfall, as PRO in the former is clearly under the obligatory control of *John*, unlike PRO in the latter, a genuine case of NOC. Nevertheless, the idea that one type of OC (though not necessarily coextensive with what Williams had in mind) reduces to syntactic predication was enormously influential and indeed, is adopted in the present work as well.

Parallel work in the 1980s continued to reformulate the duality of OC on the same, uncontested empirical grounds. Work in LFG identified Williams' OC with *functional* control (structure-sharing at f-structure) and his NOC with *anaphoric* control (coindexing with a functional anaphor, namely PRO); see Bresnan 1982, Mohanan 1983). Work in GB hypothesized that PRO is pronominal in CP complements (type (1a)) and anaphoric in IP complements (type (1b)) (Bouchard 1984, Koster 1984).

Perhaps the gravest problem with this line of research was its primary focus on English and its highly exceptional (in typological terms) *for*-infinitive construction. In fact, even within English the availability of this construction is subject to a great deal of variation. The sole criterion of allowing/disallowing a lexical subject proves to be a poor predictor of other systematic properties of C complements.³ Without abandoning the insight that OC splits into two types, later studies aimed at placing the distinction on a firmer, typologically informed empirical ground. Thus, Wurmbrand 2003 (and recently Grano 2013) capitalize on the distinction between restructuring and non-restructuring complements (equivalently for Wurmbrand, property-denoting VPs vs. propositional TP/CP complements). Landau 2000, 2004, 2006 models control on the basic operation Agree, which may apply through two "routes": directly to PRO or indirectly via C,

³ See Wyngaerd 1994:246-255 for useful discussion.

depending on whether the complement does or does not bear semantic tense. Each route is associated with its own syntactic and semantic properties.

The starting point of the present study is Landau's Agree model, and in particular, a crosslinguistic generalization stated in Landau 2004. In essence, we will distill the empirical content while discarding most of the theoretical apparatus of that work. Restating Landau's findings in terms of the predicative/logophoric distinction that was mentioned above will allow us to explore a fundamentally different approach to the duality of OC. In so doing we will follow the insights of Williams (1992) and Bianchi (2003). Williams posited the very same distinction in the realm of adjunct control, arguing that they exhibit a split between direct predication and logophoric antecedence. Bianchi assimilated control into attitude complements to logophoric dependencies, remaining neutral on the type of control operative in non-attitude complements.⁴

The structure of this study is as follows. Section 2 lays out Landau's Agree model: The fundamental assumptions, the distinction between tensed and untensed complements, the typological predictions and the formal apparatus. The section ends by listing six fundamental problems with this model that motivate a different approach. Section 3 then develops the proposal – the TTC. First, it is shown that Landau's tense distinction can (and probably should) be restated in terms of attitude/non-attitude complements; second, the notion that PRO is a minimal pronoun is proposed and defended; then predicative control is analyzed in terms of PRO-movement-as-abstraction. We next turn to logophoric control, considering and ultimately rejecting two semantic approaches to the problem of obligatory *de se*: indexical shift and local operator binding. An alternative in terms of a special *de re* presupposition is presented, whose major advantage is the natural explanation it affords for the agreement aspects of control and in particular, the crosslinguistic generalization discussed in section 2.

Section 4 broadens the empirical purview of the TTC by looking at three further distinctions that surprisingly align with the two types of control: logophoric but not predicative control requires a [+human] PRO; logophoric but not predicative control allows implicit controller; and logophoric but not predicative control allows control shift. All three distinctions straightforwardly follow from basic properties of the TTC. Section 5 offers preliminary thoughts on yet further interactions with partial and split control, controlled lexical pronouns/reflexives and noncanonical topic-control (in Philippine languages). Finally, the conclusion takes a broader look at how the results of this study

⁴ In later work, Williams (1994) claimed that predicative control (in adjuncts) involves no PRO whereas logophoric control (in adjuncts and Super-Equi) does. He also posited PRO in complement infinitives, but took the mechanism of control there to be distinct. Although the controller is often an experiencer and in that respect similar to logophoric controllers – “so similar that it is difficult to know whether logophoricity is relevant to complement control” (p. 95) – a reduction is not feasible, according to Williams, due to the existence of inanimate complement controllers (e.g. *The book served to hold open the door*). I believe that Williams' dual perception of control was just right and that he simply failed to recognize that complement infinitives display the very same duality that adjuncts do. His structural worries (that a complement infinitives cannot be a predicate of the subject, being too low) are also answered within the current conception of VP structure; see section 3.3.

shed light on control into adjuncts and NOC, raising the intriguing possibility of a higher-level unification of all control constructions under a single roof.

2. The Agree Model: Fundamentals

The Agree model of OC has been developed and expanded over a decade in a series of works.⁵ In this section I discuss the conceptual basis of the model as well as the core empirical motivation behind it. In section 2.1 I present the formal apparatus of the model and briefly illustrate its application. In section 2.2 I raise several concerns, mostly theoretical but also empirical, that call for substantial revisions in the model.

Before we lay out the model, some definitions are in order.⁶ We distinguish between OC complements and “No-Control” (NC) complements. The former host an anaphor-like null subject, OC PRO, with the familiar properties (locally controlled, sloppy reading under ellipsis, etc.). The latter host a lexical DP or a null pronoun (*pro*) subject, which are exempt from control. This distinction is *different* from the standard distinction between OC and Non-Obligatory Control (NOC), although they are occasionally (and regrettably) confused. NOC clauses typically occupy subject and adjunct positions, not complement positions, and they host a PRO subject, not a DP/*pro* subject, the former falling under logophoric interpretation. We barely touch on NOC in this study (see the conclusion for some comments) ; in fact, it is far from clear that complement clauses ever display NOC (see Landau 2013b:43-46 for discussion of this point). The choice is always between OC and NC.⁷

Second, we define a complement clause as *tensed* if its temporal coordinate need not coincide with that of the matrix clause. The definition is semantic and independent of morphological tense (i.e., there are tensed infinitive clauses and there are untensed subjunctive clauses). It also cuts across the gerund-infinitive divide, pace Stowell 1982. We recognize two types of tensed complements - realis ones (subsuming propositional and factive complements) and irrealis ones (subsuming desiderative and interrogative complements). The test for the $[\pm T]$ value of a clause consists in the (im)possibility of introducing conflicting temporal modifiers in the matrix and the embedded clauses, as illustrated below.

- | | | | |
|-----|----|---|--------------------------|
| (2) | a. | * Yesterday, John condescended to join us tomorrow. | <i>implicative-[-T]</i> |
| | b. | Yesterday, John agreed to join us tomorrow. | <i>desiderative-[+T]</i> |
| | c. | * Yesterday, Mary remembered to call us last week. | <i>implicative-[-T]</i> |
| | d. | Yesterday, Mary remembered calling us last week. | <i>factive-[+T]</i> |

⁵ See Landau 2000, 2004, 2006a, 2008. For various implementations of the model, see Adler 2006, Bondaruk 2006, Ussery 2008, Sundaresan and McFadden 2009, Sundaresan 2010, Herbeck 2011, Gallego 2011 and van Urk 2013.

⁶ The discussion here follows the detailed exposition in Landau 2013b:87-97.

⁷ Note that controlled reflexives/pronouns (Madigan 2008, Lee 2009, Szabolcsi 2009), copy and backward control (Fukuda 2008, Hornstein and Polinsky 2010) are all varieties of OC, not NC, despite the presence of a lexical subject in the complement. I assume that the mechanisms regulating these options are essentially morpho-phonological, operating *after* the OC character of the complement has been established in the syntax; see section 5.

Third and last, we define a complement as *inflected* or as [+Agr] if it carries visible inflection for ϕ -features (either on Aux or on the main predicate). This criterion sets infinitives and gerunds apart from indicative/subjunctive clauses, as well as from inflected infinitives.⁸

The [$\pm T$]-criterion breaks down control complements into two categories, each consisting of four subclasses. Sample members of these categories are given below.⁹

(3) *Predicates selecting untensed complements [-T]*

- a. Implicatives
dare, manage, make sure, bother, remember, get, see fit, condescend, avoid, forget, fail, refrain, decline, neglect, force, compel.
- b. Aspectual
begin, start, continue, finish, stop, resume.
- c. Modal
have, need, may, should, is able, must.
- d. Evaluative (adjectives)
rude, silly, smart, kind, (im)polite, bold, modest, cruel, cowardly, crazy.

(4) *Predicates selecting tensed complements [+T]*

- a. Factives
glad, sad, regret, like, dislike, hate, loath, surprised, shocked, sorry.
- b. Propositional
believe, think, suppose, imagine, say, claim, assert, affirm, declare, deny.
- c. Desideratives
want, prefer, yearn, arrange, hope, afraid, refuse, agree, plan, aspire, offer, decide, mean, intend, resolve, strive, demand, promise, choose, eager, ready.
- d. Interrogatives
wonder, ask, find out, interrogate, inquire, contemplate, deliberate, guess, grasp, understand, know, unclear.

⁸ Note that “visible morphological agreement” must be understood somewhat abstractly, as it is not required that every single slot in the ϕ -paradigm be overt. In fact, it is sufficient that some slot is overt to render the entire paradigm [+Agr]. This is a standard assumption in morphosyntax, accounting for the fact that we take the complement in *I’ve heard them sing well* to be uninflected but the complement in *I’ve heard that they sing well* to be inflected, despite the identical bare form of the verb *sing* in both cases.

⁹ These classes are largely invariant across languages, yet mismatches exist to the extent that translations of verbs do not always preserve the original conceptual structure. The lists given here are not meant to be English-specific. For example, the propositional class (4b) of English only includes two verbs (*pretend* and *claim*), but is broader in Romance and other Germanic languages.

The notion of semantic tense is closely related to (but possibly broader than) irrealis modality, which is at the core of Wurmbrand’s (to appear) revealing analysis of infinitival tense. We return below to consider the role of tense in OC.

These predicates merge with different types of complements, in different languages, to yield OC or NC. The complements may differ in category (IP vs. CP vs. DP), mood (indicative vs. subjunctive) or morphological tense (subjunctive vs. infinitive), but each one falls on a definite side of the $[\pm\text{Agr}]$ divide. The other grammatical features do not matter. The fundamental claim of the Agree model is that *all we need to know* about the control behavior of a complement (whether it displays OC or NC) are two pieces of information: the value of its $[\text{T}]$ feature and the value of its $[\text{Agr}]$ feature.

The overarching generalization is the following.

(5) *The OC-NC Generalization*

In a fully specified complement clause (i.e., the I^0 head carries slots for both $[\text{T}]$ and $[\text{Agr}]$):

- a. If I^0 carries both semantic tense and agreement ($[\text{+T}, \text{+Agr}]$), NC obtains.
- b. Elsewhere, OC obtains.

The generalization is restricted to “non-defective” complement clauses, namely standard infinitives (whose I head bears $[-\text{Agr}]$, “abstract agreement”), subjunctive and indicative complements. Excluded are raising/ECM complements and small clauses, where either $[\text{T}]$ or $[\text{Agr}]$ (or both) are entirely missing (see Landau 2004), and subject/adjunct clauses.

(5) is an elsewhere rule. The fundamental insight behind it is simple: OC is the elsewhere case of NC. In other words, the natural class is the set of clauses where lexical DPs and *pro* are licensed as subjects; PRO is licensed in a heterogeneous class of environments, specifically, whenever the I head is specified $[\text{+T}, -\text{Agr}]$, $[-\text{T}, \text{+Agr}]$ or $[-\text{T}, -\text{Agr}]$. (5) is currently the only successful description of the crosslinguistic patterning of OC and NC complements.¹⁰

2.1 Typological Predictions

Consider the typological predictions of this theory. Fully specified clauses ($[\text{+T}, \text{+Agr}]$) fall under NC. These are standard indicative clauses, as well as subjunctive clauses in many languages (e.g., Romance and Slavic), which indeed never display OC.¹¹

OC complements will be found in two contexts, as follows.

¹⁰ The typological study of Stiebels 2007 essentially replicates Landau’s results under a different terminology. Stiebels distinguishes between a syntactic and a lexical ingredient in complement control. The syntactic ingredient is the choice between control-inducing and control-neutral complements. The lexical ingredient is the choice between inherent-control predicates and structural-control predicates. These contrasts, as will be shortly seen, translate rather smoothly into $[-\text{Agr}]$ (control-inducing) vs. $[\text{+Agr}]$ (control-neutral) complements, and into predicates selecting $[-\text{T}]$ complements (control-inducing predicates) vs. $[\text{+T}]$ complements (structural-control predicates). See also Słodowicz 2008.

¹¹ Apparent counterexamples are Finnish and Brazilian Portuguese, which have been claimed to possess indicative OC complements (Rodrigues 2004, Ferreira 2009). Careful analyses, however, reveal that the said complements differ from canonical OC complements in crucial respects (e.g., the “controller” can be two clauses up); see Modesto 2007 and Holmberg, Nayudu and Sheehan 2009.

- (6) *Typological predictions: OC complements*
- a. Untensed complements (excluding small clauses) will universally be in the OC class, *regardless of inflection*. More concretely, the predicates in (3) will form the universal core of control verbs.
 - b. Uninflected complements (i.e. [–Agr]) which are nevertheless non-defective (so a [T] slot is present) will universally be in the OC class, *regardless of semantic tense*.

The predictions are confirmed across a wide range of languages and constructions, as shown in Landau 2004, 2006, 2013. What follows are sample illustrations.

Consider first (6a). Unsurprisingly, untensed and uninflected infinitives (in English and other languages) induce OC (7a). Less trivially, untensed but inflected complements still induce OC. This possibility is manifested either in controlled subjunctives in the Balkan languages (7b) or in controlled inflected infinitives in Hungarian (7c).

- (7) a. *OC in [–T,–Agr] infinitives: English*
 Mary_i remembered/forgot [PRO_{i/*j}/*Bill to lock the door].
- b. *OC in [–T,+Agr] subjunctives: Greek (Varlokosta 1993)*
 O Yanis kseri na kolimbai (*o Giorgos).
 the John.NOM knows PRT swim.3SG (*the George.NOM)
 ‘John knows how to swim.’
- c. *OC in [–T,+Agr] inflected infinitives: Hungarian (Tóth 2000)*
 Kellemetlen volt Péternek_i [PRO_{i/*j}/*pro_j/*neki_{i/j}/*Katinak későn érkez-ni-e].
 unpleasant was Peter.DAT PRO/pro/him.DAT/Kate.DAT late arrive.INF.3SG
 ‘It was unpleasant for Peter [PRO_{i/*j}/*for him/*for Kate to arrive late.’

Moving to (6b), uninflected complements always induce OC. This was already seen with untensed infinitives (7a) and it holds equally for tensed infinitives (8a). Less trivially, OC is induced in such complements even in languages that exhibit inflected infinitives elsewhere, like Welsh (8b) (note that lexical pronouns fuse with the infinitival marker in this language).

- (8) a. *OC in [+T,–Agr] infinitives: English*
 Mary_i planned/hated [PRO_{i/*j}/*Bill to lock the door].
- b. *OC in [+T,–Agr] uninflected infinitives: Welsh (Tallerman 1998)*
 Gwnaeth Elen gytuno [i / *iddi ddarllen y llyfr].
 did Elen agree to / *to.3Fem.Sg read the book
 ‘Elen agreed to read the book.’

Turning now to NC complements, the prediction from (5) is as follows.

(9) *Typological predictions: NC complements*

Complements that are tensed and inflected will be uncontrolled, *regardless of mood*.

We have already mentioned that this is the typical situation with indicative complements. Observe now that the NC character cuts across the different moods, solely depending on the presence of [+T,+Agr].¹² Tensed subjunctives in Balkan languages display NC; compare (10a) with (7b); tensed inflected infinitives in European Portuguese display NC; compare (10b) with (7c) (Hungarian has no direct counterparts); and tensed inflected infinitives in Welsh also display NC; compare (10c) with (8b).

(10) a. *NC in [+T,+Agr] subjunctives: Greek* (Varlokosta 1993)

O Yanis elpizi na figi (o Giorgos).
the John.NOM hopes PRT leave.3SG (the George.NOM)
'John hopes to leave' / 'John hopes that George would leave.'

b. *NC in [+T,+Agr] inflected infinitive: European Portuguese* (Raposo 1987)

Eupenso/afirmo [ter-em os deputados trabalhado pouco].
I think /claim to.have-3PL the deputies worked little
'I think that the deputies have worked a little bit.'

c. *NC in [+T,+Agr] inflected infinitive: Welsh* (Tallerman 1998)

Disgwylodd Aled [iddi hi/pro fynd].
expected Aled to.3Fem.Sg she/pro go
'Aled expected her to go.'

A vivid illustration of the role of agreement comes from cases where the *same* predicate selects either a [+T,-Agr] or a [+T,+Agr] complement, the mood remaining constant. Such pairs are found in languages with a sufficiently rich complementation system, like Turkish. In this language both OC and NC are realized in nominalized clauses. The nominalizing suffix *-mE* (glossed below as INF) takes either inflected or uninflected clauses, agreement being reflected by possessive markers. A predicate like *korkmak* 'afraid', which selects irrealis tense on its complement, will induce NC or OC depending on whether the complement is inflected or not (Słodowicz 2007).

(11) a. *OC in [+T,-Agr] nominalized complement: Turkish*

Ahmet_i [PRO_{i/*j} düş-mek]-ten kork-uyor-du.
Ahmet fall.INF-ABL fear-PROG-PST.3SG
'Ahmet was afraid to fall.'

¹² This statement should be qualified. In languages where agreement is radically absent (Japanese, Korean), mood particles play a decisive role in distinguishing NC from OC complements, as well as affecting the choice of controller in OC (Fujii 2006, Madigan 2008b, Lee 2009).

- b. *NC in Turkish [+T, +Agr] nominalized complement: Turkish*
 Ahmet_i [pro]_{ij} düş-me-sin-den kork-uyor-du.
 Ahmet fall.INF-3SG.P-ABL fear-PROG-PST.3SG
 ‘Ahmet was afraid that he would fall.’

[+uR], that subject must be [+iR] - namely, a lexical DP/*pro*. To match [-uR], that subject must be [-iR] - namely, PRO. A lexical DP/*pro* subject occurring with T_[-uR] or a PRO subject occurring with T_[+uR] would leave the [uR] feature on T unchecked, crashing the derivation. The OC-NC Generalization in (5) is thus captured.¹³

The more innovative part of the model also attributes the very OC effect to Agree. Specifically, a matrix functional head forms an Agree relation with a ϕ -bearing element in the infinitive – either an Agr-bundle or PRO. The matrix functional head, functioning as the probe, is the same head that agrees with the controller DP – T for subject control, light v for object control, or some applicative head for oblique controllers. [Agr] is accessible as a goal only on the C head of the infinitive, given that the next lower Agr-bundle is on T, which is lower than PRO, a potential goal itself. Thus, we have two control routes: one is direct to PRO, the other one is mediated by C.¹⁴

(14) *PRO-control*

(15) *C-control*

A number of assumptions underlie this picture. First, A “tensed” C (i.e., specified [+T]) may be selected with or without [Agr] (depending on the language, on the matrix predicate, etc.); untensed C (specified [-T]) lacks [Agr] altogether. If [Agr] is selected, the C-control route is taken, since C is closer to T/v than PRO. If C is Agr-less, PRO-control is the only option.

Second, the infinitival CP is not a strong phase in Chomsky's (2001) sense. It cannot be one since by definition, a strong phase is a syntactic substructure inside which all the features have been valued. Yet the ϕ -features of PRO are not valued until the requisite Agree relation is formed with a matrix element. The implication is that OC complements – assuming they are CPs – are weak phases.

Third, in order to transmit the necessary ϕ -values, the matrix T/v must be first valued by the controller DP; T/v then enters two Agree relations. The controller DP (in its base

¹³ The role of [uR] in distinguishing DP/*pro* from PRO in the Agree model is analogous to the role of Case in GB and minimalism. Crucially, though, the assumption in those models that PRO is caseless (or bears a special “null case”) proved untenable (see Landau 2006, Bobaljik and Landau 2009, and the references therein), hence a different distinction must be sought.

¹⁴ I abstract away from the independent Agree relation between T and C.

position) does not intervene with the second Agree relation precisely because it is the goal of the first Agree relation. This circumvention of the Minimal Link Condition is licensed by the Principle of Minimal Compliance (Richards 1998), an instance of Multiple Agree (Hiraiwa 2005).

The distinction between PRO-control and C-control is relevant to the explanation of partial control; it also interacts with case transmission in Russian in an intriguing way (Landau 2008). For now, we may abstract away from this distinction, and return to the traditional description of control as a relation between a matrix DP and PRO.

2.3 Unsatisfactory Aspects of the Agree Model

For all its success in deriving the OC-NC generalization, the Agree model cannot be the final word on control, for it raises at least seven independent problems. The problems are not unique to this specific model (most of them are shared with many other models). Nevertheless, any attempt to improve over this model must first recognize its limitations. We discuss them briefly below.

1. The stipulative R-assignment rule. Although the specification of the features [T] and [Agr] is independently motivated, and so is the distinction between DP/*pro* and PRO in terms of their [R] value, the system retains an arbitrary kernel: There is no inherent logic to the association of [+T,+Agr] with [+R] and the complementary association of other [T]-[Agr] combinations with [-R], other than a faint formal resemblance. This is no small matter, in fact it is the heart of the matter: Only by virtue of the associations in (13) can the OC-NC Generalization be captured. Furthermore, the uninterpretable variant, [*u*R], has no distinct morphological expression (nor is there any morphological reflex of its polarity), raising the suspicion that it is no more than a theory-internal convenience.

True, the Agree model is on equal footing with virtually all alternative theories of control on this fundamental point. None of them offers any insightful answer to the question of “why do certain complement types force a PRO subject and others a DP/*pro* subject”?¹⁵ As mentioned above, previous accounts were no less stipulative (invoking unmotivated assumptions about government, or factually incorrect assumptions about Case). Yet there is little solace in this equality; perhaps we can do better.

2. Triggering. The model appeals to the formal operation Agree, yet it is not clear what triggers the operation in OC configurations. It cannot be the matrix functional head, for all the uninterpretable features of that head are already checked against the DP controller by the time the complement clause is probed. What about the possibility of a low trigger? In PRO-control (14), the only candidate is the [*i*R] feature on PRO. Although

¹⁵ Actually, there is one theory that offers a principled answer: The VP-complement theory of OC (Brame 1976, Bresnan 1978, Bach 1979, Chierchia 1984, Dowty 1985, Culicover and Wilkins 1986, Jacobson 1992). On this theory, controlled subjects do not exist syntactically, hence the issue of their nullness is trivially resolved. There are, however, incontrovertible reasons to believe in the syntactic reality of PRO (see Landau 2013b for a summary of relevant arguments). Moreover, the issue is not so much the nullness of OC PRO - for there are overt controlled subjects, see section 5 - but its necessarily anaphoric nature.

interpretable, this feature is anaphoric, and presumably Agree with a valued antecedent “satisfies” it. The intuition is clear, but whether Agree is capable of delivering such semantic outcomes is less clear. In C-control (15), however, there is not even a candidate for a low trigger; the $[-uR]$ on C can be checked against $[-iR]$ on PRO (and the same for $[-Agr]$). Not being interpretable itself, $[-uR]$ is not an anaphor. This still leaves the anaphoric $[-iR]$ on PRO without a valued antecedent, but again, falls short of providing direct triggering (Agree (T_{Matrix}, C) would have to be “altruistic” for the benefit of PRO).¹⁶

3. The coherence of "semantic tense". Recent work suggests that the notion of "semantic tense" is more nuanced than what Landau assumed. On the basis of sequence-of-tense diagnostics, Wurmbrand (to appear) distinguishes between simultaneous (aspectual and implicative) infinitives, which project up to Asp(ect)P, modal (irrealis) infinitives and zero-tense (propositional) infinitives; none of them, according to Wurmbrand, contain contentful tense, although they give rise to different temporal interpretations. Following up on her results, Grano (2012) points out "oddballs" for the Agree model: EC predicates that allow temporal mismatch (thanks to modality) and PC predicates that do not. These developments suggest either that the PC class is linguistically spurious, or that it is real alright but what makes it stick together is not tense but some other linguistic concept.

4. The Status of PRO. It is no secret that PRO is a sore thumb in the eyes of many linguists. The problem is not so much its nullness (although certain frameworks, e.g., Categorical Grammar, are already averse to this property) as its uniqueness to control environments. Attempts to reduce PRO to more fundamental elements go back to the GB era and form a cornerstone of the present-day Movement Theory of Control (Hornstein 1999, Boeckx and Hornstein 2006, Boeckx, Hornstein and Nunes 2010). The most popular ideas are to view PRO either as an anaphor or as a copy (trace) of movement. In contrast, the Agree model did not concern itself with eliminating PRO but simply suggested that it is an anaphoric element "of sorts" (akin to SE anaphors). Moreover, the reduction of PRO to trace raises numerous empirical difficulties.¹⁷ The question remains - why is PRO confined to control environments? Any theory which takes PRO to be a nominal element that can, in principle, occur elsewhere, is to be preferred on grounds of conceptual simplicity (assuming the theory passes the hurdle of empirical adequacy, a pre-requisite for this kind of considerations).

5. The (lack of) relation between OC and NOC. Early generative treatments of control upheld a uniform structural constraint on both OC and NOC (Grinder 1970), but this position was soon discarded on empirical grounds (see Landau 2013b for a historical overview). Two alternatives emerged: (i) PRO in NOC is a pronoun; (ii) PRO in NOC is a logophor. Crucially, on either approach, OC PRO is an unrelated category (anaphor, trace, variable, etc.). The Agree model adopts the logophoric analysis of NOC, which proves to be superior to the pronominal analysis. Yet it too falls short of bridging the gap between the identity of OC PRO and the identity of NOC PRO. Correlatively, the

¹⁶ Note that this problem in the Agree model is directly inherited from its precursor, the anaphoric Agr theory of Borer 1989.

¹⁷ See Landau 2003, 2007, 2013a, Bobaljik & Landau 2009, Sato 2011, Ndayiragije 2012, Wood 2012.

mechanisms involved in the assignment of reference to the two elements are sharply distinguished (OC being determined jointly by the lexicon and syntax, NOC being a discourse phenomenon). While the empirical differences are undeniable, it is legitimate to ask whether they run as deep as an ontological duality of PRO rather than reflecting higher-level grammatical distinctions which nonetheless hide a unitary structure.

6. Semantic groundedness. The model is chiefly concerned with agreement and feature transmission, but says very little about the interpretation of OC constructions. Once again, this is not a problem specific to the Agree model, and yet it is one which should ultimately be addressed in a comprehensive theory of control. Landau proposes that Agree establishes coindexing, which in turn is interpreted as variable binding (more precisely, the controlling and the controlled thematic positions are variables co-bound by the same operator). One hopes to see a more explicit account of the syntax-semantic interface in OC constructions, which would also address the less canonical situations of partial and split control.

7. Oblique control. When the controller is a prepositional object (e.g., *We demanded from him to turn himself in*, *Can I impose upon you to share this information with us?*), the matrix probe is the applicative head that licenses the controller. This assumption is problematic in two respects. First, PPs are presumably precisely the kind of arguments that are *not* introduced by applicative heads; the latter are called upon to integrate bare DP arguments (Baker 1988, Marantz 1993). Second, even if such an applicative head exists, it is unlikely to register the ϕ -features of the prepositional object. Such objects typically do not control agreement; when they do, the agreement shows up on the preposition that governs them (Baker 2008) and not on any functional head in the verbal projection. But in the absence of a functional head that registers the ϕ -features of the controller DP, there is no probe for the Agree operation that establishes OC. This is a serious problem, for oblique control is a very common option in many languages.

After developing the new analysis of control, we return to these issues in section 3.7.

3. A new proposal: predication vs. logophoric anchoring

This section develops a comprehensive theory of obligatory control that supersedes the Agree model. Discarding much of the technical apparatus of that model, we retain its major two achievements: First, the dichotomy between EC and PC complements, and second, the OC-NC generalization. Both of these achievements will have to be restated so as to make them amenable to a rather different treatment of control, paying closer attention to semantic considerations.

In section 3.1 I recast the EC-PC distinction in terms of the underlying semantic notion of attitude reports: PC verbs are attitudinal while EC verbs are not. Section 3.2 proposes that PRO is treated as a minimal pronoun in *all* of its manifestations. Section 3.3 presents the analysis of EC complements as a type of predication, made possible by the movement of PRO which abstracts over the complement. PC complements are analyzed in section 3.4: After discussing the shortcomings of two alternative accounts (indexical shift and local

binding of a logophor), I propose that logophoric control is constructed as a second tier above the structure produced for predicate control; the link to the matrix clause is established by a bound variable denoting a coordinate of the embedded context and projected as an argument of the complementizer, which also introduces the special *de se* presupposition. How the two modes of control support agreement between the controller and PRO is addressed in section 3.5, which forms the basis of section 3.6, where the OC-NC generalization is fully derived. Section 3.7 returns to the problems that were noted in the Agree model and shows how they are solved within the new system.

3.1 Attitude and non-attitude contexts: restating the split

So far, we have seen that the two types of OC complements differ in two respects. One type is semantically untensed and rejects partial control (EC-complements); the other type is semantically tensed and allows partial control (PC-complements). These two properties are correlated in Landau 2000 via certain assumptions about the way [T] and [Agr] bundle in control complements. Importantly, the underlying intuition was that the two properties are not ontologically symmetric, one being a theoretical primitive, the other a derivative. It is the contrast in [\pm T] that explains the contrast in (the partiality of) control, and not vice versa. What I would like to propose now is a shift in perspective, whereby *both* properties stem from a yet deeper, third distinction: whether the complement is selected by an attitude predicate or not.¹⁸

Attitude contexts are domains in which the denotation of linguistic expressions is determined relative to the epistemic or bouletic state of a participant in the reported situation and not relative to the actual world. Insofar as specific descriptions may mean different things for different people (i.e., pick different referents in their respective belief worlds), referential expressions are known to give rise to the *de re-de dicto* ambiguity. Thus, the presence of such an ambiguity is a standard test for attitude contexts (and its absence, for non-attitude contexts).¹⁹

Because it is ambiguous between the two readings, a definite description cannot be substituted *salva veritate* inside an attitude context, the way it can inside a non-attitude context. Suppose Ralph, an old acquaintance of Bill, has been appointed the new boss in Bill's office, but Bill does not know this yet. The following contrast in the entailment patterns indicates that the complement of *see* is not an attitude context whereas that of *imagine* is.

- (16) a. Bill saw Ralph jogging in the park.
 \Rightarrow Bill saw the new boss jogging in the park.

¹⁸ Bianchi (2003) observed that PC verbs are attitudinal while EC verbs are not. Pearson (2013) reasserts the distinction in these terms but places propositional complements (without aspectual markers) in the EC class.

¹⁹ Note that attitude contexts are, by definition, intensional, but non-attitude contexts are not necessarily extensional. Complements of modal predicates (e.g., (17a)) are intensional non-attitude contexts.

- b. Bill imagined Ralph jogging in the park.
- ⇒ Bill imagined the new boss jogging in the park.

In this light, consider EC and PC control verbs. It is easy to see that modal, aspectual and evaluative predicates select non-attitude complements, whereas desiderative, propositional and interrogative predicates select attitude complements. The examples below are representative of each subclass; they should be evaluated in the context introduced above.

(17) *EC complements: non-attitude contexts*

- a. Bill should greet Ralph. *modal*
- ⇒ Bill should greet the new boss.
- b. Bill started to talk to Ralph. *aspectual*
- ⇒ Bill started to talk to the new boss.
- c. It was rude of Bill to ignore Ralph. *evaluative*
- ⇒ It was rude of Bill to ignore the new boss.

(18) *PC complements: attitude contexts*

- a. Bill planned to meet Ralph soon. *desiderative*
- ⇒ Bill planned to meet the new boss soon.
- b. Bill pretended to be Ralph. *propositional*
- ⇒ Bill pretended to be the new boss.
- c. Bill asked where to take Ralph for lunch. *interrogative*
- ⇒ Bill asked where to take the new boss for lunch.

It is slightly less obvious that implicative verbs (especially those involving an experiencer subject) select non-attitude complements.²⁰ To see that this is indeed the case, contrast implicative with factive verbs, which take attitude complements. The contradiction test is equivalent to the entailment test but is somewhat easier to judge.

- (19) a. Bill remembered to greet Ralph, *implicative*
- # but he didn't remember to greet the new boss.
- b. Bill remembered greeting Ralph, *factive*
- but he didn't remember greeting the new boss.

Suppose the second conjunct of (19a) were true. If Bill didn't remember to greet the new boss, it follows that he didn't greet the new boss, which entails, in turn, that he didn't greet Ralph. But if he didn't greet Ralph, then the first conjunct of (19a) would be false, contrary to the assertion. The second conjunct of (19b), on the other hand, does not entail that Bill didn't greet the new boss (in fact, it retains the entailment that he did). Not

²⁰ In fact, Pearson (2013) calls them "non-canonical" attitude verbs, but concedes that their semantics does "not involve quantification over world-time-individual triples" (p. 426). I therefore find the attitudinal terminology misleading and prefer to class them with non-attitude verbs.

knowing who Ralph was, Bill may have no memory of greeting *the new boss*, so the two conjuncts are consistent.²¹

As Pearson (2013:406) observes, implicative complements are not semantically opaque, and so indefinite DPs inside them carry existence entailments, unlike their behavior inside attitude complements.

- (20) a. # John dared/remembered/saw fit to ride a unicorn.
b. John wanted/refused/agreed to ride a unicorn.

We can now restate the basic split in the domain of OC.

- (21) Non-attitude complements are untensed and force EC;
Attitude complements are tensed and allow PC.

One can see why the two types of complements might differ in their temporal properties. Attitude domains are evaluated relative to alternative (non-actual) contexts, and one coordinate of such contexts is the time coordinate; thus, John's belief worlds may be situated in the past (if he is thinking of past events) and his bouletic worlds are situated in the future (in which his desires will be fulfilled). So the presence of semantic tense is a by-product of attitude contexts; put in grammatical terms, [+T] is introduced by attitude operators.

Reference to semantic tense in infinitives may be, however, misguided, in view of recent evidence that there is no semantic tense in them (Wurmbrand, *to appear*); rather, irrealis infinitives contain a modal operator and other infinitives are either tenseless or contain a “zero tense”. If this is true, the present discussion allows us to discard all reference to tense in describing control complements, by simply focusing on the attitude property.²²

- (22) Non-attitude complements force EC; attitude complements allow PC.

This feature of the new picture improves over the original Agree model. In that model, the [\pm T] distinction was a stipulated selectional distinction imposed by the matrix verb. This is not to say that it was arbitrary; being a semantic property, it was couched in the lexical semantics of different control verbs. Nevertheless, the distinction was *unrelated* to any other semantic aspect of control verbs, thus missing the robust correlations in (22). Viewing the tense contrast as a manifestation of the deeper contrast in (non)attitude contexts removes this anomaly. Furthermore, we will shortly see that the attitude operator introduced by PC verbs carries more information beyond (a possibly null) tense -

²¹ The sharpness of the judgment in (19a) is potentially obscured by the interference of a metalinguistic negation reading of the second conjunct, whereby *the new boss* is heavily stressed. This reading can be blocked by using a negative polarity item in the complement, which can only be licensed by logical negation. The contrast between the implicative (i) and the factive (ii) is unmistakable.

i. Bill remembered to give something to Ralph, # but he didn't remember to give anything to the new boss.
ii. Bill remembered giving something to Ralph, but he didn't remember giving anything to the new boss.

²² Some thoughts on why PC is limited to attitude complements will be offered in section 5.

specifically, logophoric coordinates coding the speech event participants - that is constitutive of the control dependency. Thus, there is little doubt that the shift in perspective is a step forward in the understanding of the mechanisms of control.

The attitude/non-attitude distinction allows not only a restatement of the EC-PC contrast, but also of the OC-NC contrast; that is, the very generalization regulating the distribution of OC complements. The OC-NC generalization in (5) states that the co-occurrence of semantic tense and agreement on a complement's head blocks control. Since semantic tense is now replaced by an attitude context, and the latter induces logophoric control, we can restate the generalization as a contrastive effect of inflection on the two types of control. Again, direct reference to tense is unnecessary.

(23) *The OC-NC Generalization (restated)*

[+Agr] blocks control in attitude complements but not in non-attitude complements.

Or:

[+Agr] blocks logophoric control but not predicative control.

Equivalently, a complement clause whose head is inflected for ϕ -features may either display predicative control or no control at all, but may not display logophoric control. Explaining this curious interaction is the task of section 3.5 below. We now turn to lay out the formal analysis of the two types of control, starting with what they share – the element PRO.

3.2 PRO as a bound minimal pronoun

Predicative and logophoric control complements display very distinct properties. We already mentioned that predicative complements are non-attitude contexts that impose EC, while logophoric complements are attitude contexts that allow PC. Further contrasts, to be discussed below, include *de se/de re* readings, tolerance to implicit control and control shift. One may ask whether the distinction goes down to the level of the controlled element. That is, are there two types of OC PRO, one occurring in predicative complements, the other in logophoric ones, each associated with its own characteristic interpretation?

The is not far-fetched, and in fact, the semantic literature develops various proposals along these lines. The idea is that in attitude OC complements, PRO is bound by a logophoric or context-shifting operator, lexically encoded in the attitude predicate or syntactically present as an operator in the C-domain of the complement. This binding relation generates the obligatory *de se* interpretation. To guarantee the binding relation, PRO is "flagged" by a diacritic: [+author] in Schlenker 2003 (reflecting the 1st person perspective of *de se*), [log] in Anand 2006 (matching the logophoric operator), [log] in Maier 2011 (triggering an acquaintance presupposition of identity to the attitude holder), both [log] and [loc] in Stechow 2003 (the latter encoding the necessary locality of the operator to PRO), and [J] in Stephenson's 2010 centered-world treatment (referring to the perspectival "center").

There are a number of problems with this family of proposals. First, as Anand (2006:63) admits, they are openly stipulative, reifying basic structural and interpretive aspects of OC as lexical markers instead of deriving them from deeper principles. Second, they raise several empirical as well as theoretical difficulties (see sections 3.4.2-3.4.3 below). Third, there is no causal connection whatsoever between the form of PRO and its featural content. Why is it overwhelmingly the case that a bound variable with any of these diacritics ends up being phonetically null?²³ On some proposals, PRO is featurally identical to logophoric pronouns, which are of course overt. The difference is in their licensing environments, but again, it is not clear what is it about the environments that makes PRO null and logophoric pronouns overt. These are the kind of questions that an integrated theory of control must address.

The final problem with the semantic proposals is that they cannot extend to instances of PRO in non-attitude contexts, where no logophoric (or context-shifting) binder is present in C. It was already Chierchia (1990) who observed that any attempt to pin down the *de se* reading of OC PRO to some inherent feature it bears would falsely predict that all instances of OC PRO should support this reading.²⁴ In fact, quite a few OC contexts are free of the *de se* entailment. These are precisely the contexts of predicative control, unmediated by a logophoric operator. Note that the controller need not be human, and even when it is, it bears no first-person epistemic relation to the embedded event (see also Safir 2010, from which examples (24a-b)/(25a,c-d) are drawn, Sundaresan 2010, Pearson 2013:541 and Landau 2013b).

- (24) a. This key_i will serve/do [PRO_i to open the door].
- b. The accident_i is responsible [for PRO_i causing the ship to sink].
- c. The apartment_i failed [PRO_i to meet the federal housing quality standards].
- d. The transmission problem forced the car_i [PRO_i to stop].

- (25) a. Mavis screamed at/mumbled to Toby_i [PRO_i to batten the hatches]
(but he never heard her).
- b. The head of ceremony signalled to the amnesiac_i [PRO_i to leave the stage].
- c. John_i managed [PRO_i to avoid the draft] (because he spent that decade
in a coma).
- d. Mary_i neglected [PRO_i to send the payment].

Other instances of nonlogophoric PRO involve infinitival main predicates, subject relatives and subject purpose clauses.

- (26) a. [This cheesecake]_i is [PRO_i to cheer you up].
- b. I wait to hear the song_i [PRO_i to be selected].
- c. I bought this blender_i [PRO_i to help me make split pea soup].

²³ We return in section 5 to account for the exceptional cases of controlled pronouns and reflexives.

²⁴ To be fair, Chierchia realized that OC PRO must be locally bound (unlike other bound pronouns), a property he left underived.

In face of examples like (24)-(26), the semantic proposals mentioned above would be forced to posit a second kind of PRO, basically a simple λ -abstracted variable. Thus, they are committed to a dual analysis: $\text{PRO}_{[\text{author/log/loc}]}$ in attitude contexts, and a simple PRO elsewhere. This seems like a suspicious duplication of the grammatical information already present in the two types of contexts PRO occurs in: Attitude and non-attitude contexts. A preferable solution would posit a *single* element PRO, unspecified for any particular interpretation. Specific meanings would arise from the grammatical contexts rather than from any inherent feature on PRO.

This leads to a radically impoverished view of PRO; a "reference variable" in the sense of Sigurðsson 2008 or a "minimal pronoun" in the sense of Kratzer 2009. I will adopt this view in what follows. For concreteness, assume the following lexical entry ($[\phi:]$ stands for unvalued ϕ -features).

(27) *A minimal pronoun*

X is a minimal pronoun iff $X = [D, \phi:]$.

Note that X can become, within different derivations, a bound lexical pronoun, a resumptive pronoun, a *pro* element identified by local agreement, a relative pronoun, or indeed, controlled PRO. Thus, PRO is but one realization of the generalized grammatical element, a minimal pronoun. This view eliminates the "specialness" of PRO, a sore thumb for most earlier accounts (see point 4 in section 2.3). I take it that any account that multiplies the lexical entry of PRO beyond this single, minimal element, bears a rather heavy burden of proof. This consideration will be very effective in narrowing down the available analytic options in what follows.

As for the distinction between predicative and logophoric control, the minimal pronoun approach places the explanatory burden on the detailed specification of the syntactic and semantic ways in which these two environments are distinguished. We now turn to provide a formal analysis of the two cases, starting with predicative control first.

3.3 Predicative control: PRO-movement

Predicative control is found with four classes of predicates (see (3)): aspectual, modal, implicative and evaluative. As discussed in section 3.1, the complements of these predicates are non-attitude contexts.

- (28) a. Mary began to paint the wall.
 b. Mary is able to paint the wall.
 c. Many saw fit to paint the wall.
 d. It was smart of Many to paint the wall.

Note that the embedded event is only entailed in (28c-d); in (28a) only the beginning of the process of painting is entailed, while in (28b) there is reference to a potentiality (the embedded event holds in all of the possible worlds in which Mary's abilities are materialized). The non-attitude property reflects the fact that the evaluation of the

embedded event does not depend on the epistemic or bouletic state of the controller, *Mary*, but rather on physical or external conditions.²⁵

As an example, let us consider the verb *begin*, using the semantics of the progressive aspect as a model (Condoravdi 2009); for a comparable treatment of implicative verbs, see Pearson 2013:410-413. If John began to paint the wall in world *w*, then John has painted the wall to some degree *d* (lower than 1) in *w*; further, it is reasonably expected that in some world *w'* where things develop in ways most compatible with the past course of events in *w*, called an *inertia world* of *w*, John paints the wall to a greater degree.

(29) *Definitions*

- a. $IN_w =_{\text{def}} \{w': w' \text{ is an inertia world of } w\}$
- b. $e \subset e' \text{ iff } e \text{ is an initial sub-event of } e'$

The denotations of the predicative complement and the control verb are given below.

- (30) a. $[[\text{to paint the wall}]]^{w,g} = \lambda d'. \lambda x. \lambda e'. e' \text{ is an event of } x \text{ painting the wall to degree } d' \text{ in } w.$
- b. $[[\text{begin}]]^{w,g} = \lambda P_{\langle d, \langle e, \langle s, t \rangle \rangle \rangle}. \lambda d'. \lambda x. \lambda e'. P(d', x, e') = 1 \text{ in } w \wedge \exists \langle e'', w'', d'' \rangle [w'' \in IN_w \wedge e' \subset e'' \wedge d' < d''], P(d'', x, e'') = 1 \text{ in } w''.$
- c. $[[\text{begin to paint the wall}]]^{w,g} = \lambda d'. \lambda x. \lambda e'. e' \text{ is an event of } x \text{ painting the wall to degree } d' \text{ in } w \wedge \exists \langle e'', w'', d'' \rangle [w'' \in IN_w \wedge e' \subset e'' \wedge d' < d''], e'' \text{ is an event of } x \text{ painting the wall to degree } d'' \text{ in } w''.$

Importantly, the predicative relation between *Mary* and *to paint the wall* is established syntactically and is visible both to LF and PF. In other words, in predicative control, the relation between the complement and the controller is registered at all grammatical levels and not just in the semantics. This of course echoes the line of research originating in Williams 1980, where predication was conceived as a core syntactic relation. We follow this intuition with one important departure: For us, syntactic predication accounts only for one subtype of OC (in fact, the less frequent one); logophoric control utilizes a different device (see the next section).

Let us now spell out the syntax of predicative control. The two key components in any predication relation are a referential argument and a predicate. In predicative control, the

²⁵ This is also true of evaluative predicates, as in (28d), which, pace Stowell Stowell 1991, do not implicate the mental state of the controller but merely judge his/her behavior from an external point of view (see Landau 2009 for discussion). As discussed above, implicative verbs do introduce an experiencer, but his/her mental state does not affect the evaluation of the complement, which is uniformly entailed. Pearson (2013:411), following Grano's (2012) analysis of *try*, encodes the intentions of the experiencer via an ordering source.

former is the controller and the latter is the infinitive.²⁶ The two stand in a mutual m-command relation, which is standardly taken to be the relevant locality condition on syntactic predication.

If the complement to the control verb is a lexical projection, predication is straightforward, since lexical projections can function as natural predicates. Such is the case in radical restructuring, where the infinitive hosts no structural subject and projects to the VP level only (Wurmbrand 2003, Grano 2012). I set aside this option, which does not seem to raise any particular difficulty.

More interesting are situations where the infinitive is headed by some functional category (Asp, T, Fin, etc.). These categories project phrases which are not natural predicates, and become predicative only with the aid of a syntactic operator. Thus, a clause is turned into a predicate by an operator merged at its edge, either externally or internally (by movement); the operator is later translated as a λ -abstractor. This device is put to use in relative clauses, *tough*-constructions, object purpose clauses, parasitic gap constructions, left dislocation and copy-raising constructions (see Landau 2011 for a recent discussion).

Is the operator in predicative control merged externally or by movement? The two options are semantically equivalent but there may be syntactic reasons to favor one over the other. I will mention below some reasons for preferring the movement option. Under this analysis, the operator is nothing but PRO itself, moving to the specifier position of the infinitival complementizer. This is, of course, not a new idea. It was Chomsky (1980) who first proposed PRO-movement as a means of producing syntactic predication in infinitival purpose clauses. Hendrick (1988) recruited PRO-movement for relative clause formation in general, and Clark (1990) extended it to all OC constructions. Our implementation follows the insights of Clark, but restricts them to predicative control only.²⁷

The derivation of predicative control proceeds as follows. An infinitival TP with a PRO subject is embedded under a "predicative" head in the low CP periphery. I will designate this head as Fin (Rizzi 1997), reserving the label C for the head of logophoric control complements; nothing crucial rests on these labels, however. Like the C-head of a relative clause, Fin attracts an operator to its specifier. Unlike the former, though, the latter requires a nominal operator, i.e., a D category; call this Fin head a *transitive Fin*. Let us encode this property by an uninterpretable feature on Fin, [*uD*], that acts as a probe searching for a matching D category. The closest one is of course PRO, in [Spec,TP], which is therefore pulled up and remerged in [Spec,FinP]. The predicative FinP is subsequently merged as a complement of the lexical control verb, in the case of subject

²⁶ We consider below the possibility of a third component – a predicative head, or relator, mediating between the argument and the predicate (Bowers 1993, den Dikken 2006).

²⁷ Percus and Sauerland (2003b) employ pronoun-movement in finite clauses to achieve predicate abstraction, which derives *de se* readings on the property view of *de se* (Lewis 1979, Chierchia 1990). We will derive *de se* readings differently, using Percus & Sauerland's other device of "concept generators" (see section 3.4.4).

control, or the complement of a causative small clause, in the case of object control. We illustrate the former first.

(31) *Derivation of predicative subject control*

A few comments on this derivation are in order. As defined in (27), the embedded subject is nothing but a minimal pronoun; we retain the symbol 'PRO' for expository convenience only. We also suppress higher projections in the CP periphery, which could serve as landing sites for focus or *wh*-elements. Just like infinitival complements of *tough*-constructions are not rendered islands by the occurrence of a null operator at their edge, (e.g., *Where are red pebbles most difficult to find?*), standard control complements are not either.

A major benefit of this analysis is that it automatically delivers the fundamental distributional property of control – the subjecthood of PRO. The controlled nominal is the one that is attracted to [Spec,Fin] and creates the λ -abstract. Since this movement is triggered by feature checking (to satisfy [uD] on Fin), which is subject to the Minimal Link Condition, the attracted nominal must be the closest one to Fin, namely, the subject.

Thus, the subjecthood of PRO is derived with no recourse to unmotivated stipulations concerning case or government (see McFadden 2005 and Landau 2006 for discussion).

Furthermore, placing the triggering feature on the Fin head (selected by the control verb) rather than on PRO immediately explains why PRO's movement is maximally local. Compare, in this regard, the related proposal of Pearson (2013:536), where PRO is also treated as a (minimal) abstractor that undergoes \bar{A} -movement to the edge of its clause. Differently from the present proposal, Pearson stipulates that PRO is inherently specified as a pronoun that "must move". Putting aside implementation – exactly what syntactic feature has that consequence? – this wrongly permits long-distance movement of PRO (just like relative pronouns), overgenerating examples like **Mary_i said [PRO_i that John claimed [_{t_i} _{t_i} to be true to herself]]*. As far as I can tell, even the necessary subjecthood of PRO is not derived on this analysis.

Another noteworthy feature of the structure in (31) is that the predicative relation is an emergent property and not encoded in any specific ingredient. Thus, unlike related proposals in the literature, there is neither a [+pred] feature nor a designated "Operator" here. λ -abstraction is an automatic outcome of movement (Heim and Kratzer 1998). The fact that the moved element (PRO) does not saturate the λ -predicate thereby formed simply follows from it being nonreferential. In other words, the radical impoverishment of a minimal pronoun allows it to turn into an operator, once moved. The trace of PRO, equally devoid of content, serves as the variable abstracted over. From the standpoint of LF, PRO is nothing but a numerical index, interpreted as an operator in [Spec,FinP] and a variable in [Spec,TP], the difference being purely configurational (contingent on movement) and not inherent. Precisely in virtue of lacking any intrinsic content, PRO in predicative control imposes no semantic restrictions on its antecedent (24), just like PRO in other predicative environments does not (26).

In (31), the complement comes to denote the predicate $\lambda x.x \text{ stay healthy}$. This predicate is truly nonpropositional, lacking any temporal specification (see (3)). Thanks to V-to-v raising in the matrix clause, the m-command domain of the complement is the matrix vP. Syntactic predication is thus licensed, with *v* serving as the *relator* in den Dikken's (2006) sense. In the semantics, after λ -conversion, the *i* and *j* indices collapse, obtaining the saturated state of affairs *stay-healthy(John)*. The implicative verb, of course, makes its own contribution to the overall interpretation.

Another basic property of OC complements - the ban on lexical subjects - is derived too. Suppose a lexical DP is merged as the internal subject of the embedded vP and raised through [Spec,TP] to [Spec,FinP], as in (32a). Then FinP comes to denote a proposition (type $\langle s, t \rangle$), in violation of the lexical requirement of the control verb, which selects a property (type $\langle e, \langle s, t \rangle \rangle$, abstracting away from the degree argument) as an internal argument (cf. (30b)).²⁸ The same is true if both a lexical DP and PRO are merged in the

²⁸ Details of implementation aside, this is essentially the explanation offered by Chierchia (1984). By contrast, Grano (2012) assumes that non-attitude complements are propositional; the reason they cannot host a lexical subject is syntactic, the matrix verb actually being a *raising* (restructuring) verb. Space limitations do not allow me to compare this alternative with the present proposal.

complement clause and PRO only moves as high as [Spec,TP], (32b). If it is the DP that moves and PRO stays, (32c,d), the structure is presumably uninterpretable, since vP denotes a proposition, which cannot combine with the nominal in [Spec,Fin] via predication. In addition, (32c,d) incur a violation of the θ -criterion, the DP and PRO competing over a single θ -role.

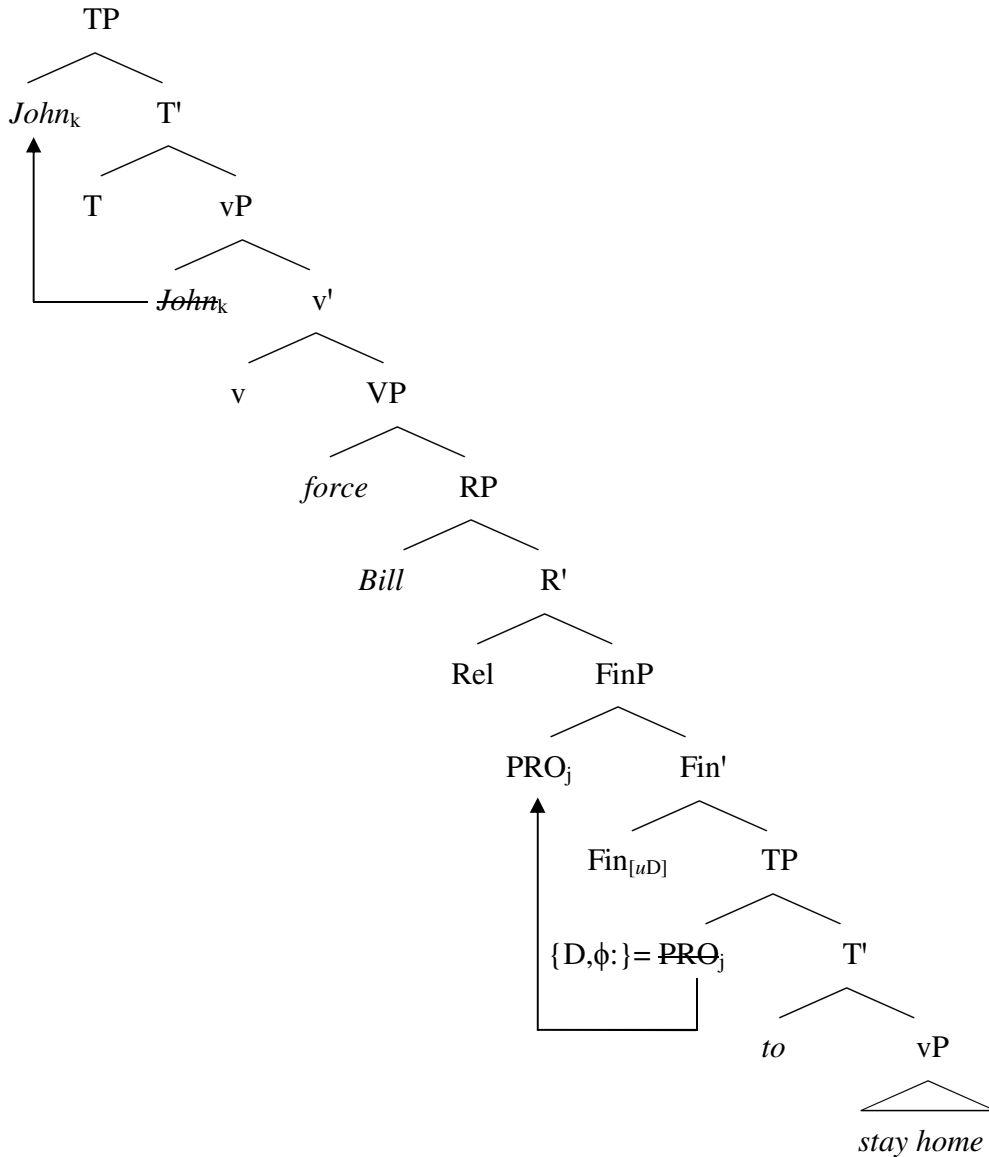

- (32) a. * [_{FinP} DP Fin [_{TP} t_i T [_{VP} t_i v [_{VP} ...]]]]
 b. * [_{FinP} DP Fin [_{TP} PRO_i T [_{VP} t_i v [_{VP} ...]]]]
 c. * [_{FinP} PRO Fin [_{TP} DP_i T [_{VP} t_i v [_{VP} ...]]]]
 d. * [_{FinP} DP_i Fin [_{TP} t_i T [_{VP} PRO v [_{VP} ...]]]]

The question remains why PRO cannot be replaced by a lexical pronoun; in traditional terms, what explains the nullness of PRO? In fact, this property is common but not universal; in section 5 I return to discuss the privileged status of null forms as the choice for minimal pronouns, both in predicative and in logophoric control.

Turning to predicative object control, its structure is slightly more complex. Observe that this rather small class consists of implicative verbs only, all of which are semantically causative (*force*, *compel*, *coerce*, *impose*). Assume, then, that the object controller and the infinitive occupy the subject and predicate positions of a small clause, projected by a predicative head, or a relator; RP is the maximal projection of this relator, serving as the complement of the causative verb.²⁹

²⁹ Franks and Hornstein (1992) propose that object controllers form a small clause with the infinitive, although their empirical argument - the alleged absence of case transmission into object control infinitives in Russian - was subsequently falsified in Landau 2008. Mulder (1991) argues, very much in the spirit of the present proposal, for a null predicative head relating the object controller and the infinitive. Differently from the present proposal, which is confined to predicative control, these analyses apply to *all* object control constructions.

(33) *Derivation of predicative object control*

On the PF side, syntactic predication is a vehicle of agreement; all ϕ -features of the subject are copied onto the predicate. The details of this process are elaborated in section 3.5. Because syntactic predication is a highly rigid relation, predicative control exhibits a number of restrictions of which the other type of control – the logophoric type – is free. We return to these contrasts in section 4. Surprisingly, it is less restricted in one empirical domain – the interaction with inflection. As stated in (23), predicative control holds regardless of inflection whereas logophoric control is contingent on the absence of [+Agr]. The reason for this independence of syntactic predication and inflection will become clear in section 3.6.

Finally, let us point out one side-benefit of the particular view we take on transitive-predicative complementizers. The feature on Fin responsible for attracting the PRO operator, we suggested, is [*u*D]. Note that this feature characterizes another syntactic category – prepositions. The category P is defined by the very same selectional property: it selects a nominal complement. From this perspective, it is anything but surprising that nonfinite (control) complementizers, both synchronically and diachronically, are so frequently prepositional in form and origin: the two functional categories share the [*u*D] feature (in addition to which, the complementizer bears a [*u*T] feature). In fact, this striking morphosyntactic overlap is an accident for most approaches to control, and would remain so even if the relevant feature on Fin were [+pred]/[+Op] (which are not defining features for prepositions anyway).

3.4 Logophoric control

There has been intensive research on the syntax and semantics of attitude reports and logophoricity in recent years, which has produced some interesting and non-trivial results. These results have mostly been demonstrated in the realm of finite complementation to declarative and epistemic verbs; my goal in this section is to pursue their full implications for the analysis of OC. By nature, this analysis will be a highly integrative.³⁰

In section 3.4.1 I survey the theoretical terrain of *de se* ascriptions, focusing on three types of mechanisms achieving them (indexical shift, local operator binding and special *de re* ascriptions). In section 3.4.2 I summarize the arguments against the indexical shift view and in section 3.4.3 I summarize the arguments against the local operator binding view. Section 3.4.4 develops the proposed analysis, in which the embedded C projects an argumental variable, bound by the controller and associated with a special *de re* description; this argument then saturates a predicative FinP projection, formed by PRO movement just as in predicative control. Further implications of this analysis for the interaction of OC with agreement are explored in section 3.5.

3.4.1 The theoretical terrain

Logophoric control is manifested in four classes of complements: propositional, factive, desiderative and interrogative (see (4)). As shown in section 3.1, the predicates selecting these complements are attitude predicates.

- (34) a. Mary claimed to have found the solution.
 b. Mary was shocked to find the solution.
 c. Mary intended to find the solution.
 d. Mary asked how to find the solution.

³⁰ For studies of the syntax of the left periphery related to attitude reports and logophoricity, see Koopman and Sportiche 1989, Bianchi 2003, Sigurðsson 2004, Speas 2004, Adesola 2005, Baker 2008, Giorgi 2010, Sundaresan 2012. For studies of the semantic aspects, see Chierchia 1990, Schlenker 2003, 2011, Percus and Sauerland 2003a, von Stechow 2003, Safir 2004, Anand and Nevins 2004, Anand 2006, Stephenson 2010, Maier 2011, Pearson 2013.

Note that only the factive complement, (34b), is entailed (being presupposed), the other complements are not. The attitude property reflects the fact that the evaluation of the complement crucially depends on the epistemic or bouletic state of the controller, *Mary*, over and above any physical or external conditions.

The embedded predicate enters a certain semantic relation with the controller, but differently from predicative control, the relation is indirect. For example, (34c) does not entail that Mary found the solution but only that she did so in those possible centered-worlds in which her intentions come true (Chierchia 1984, Dowty 1985). More importantly, a specific interpretive condition holds to the effect that Mary's intention concerns her own self, and so would not be satisfied if she does not identify herself as participating in the intended event. This is the famous *de se* reading, which is often taken to be definitional of PRO in OC. As already discussed in section 3.2, this view is false - PRO in predicative control is not necessarily *de se* - and its falsity is a strong argument in favor of the minimal pronoun view of PRO. Is it true, though, that under predicates of logophoric control, PRO is obligatorily interpreted *de se*?

In reality, the situation is slightly more complex; it is summarized in (35).

(35) *Interpretations of OC PRO under attitude predicates*

Type	Subject control	Object control	
Examples	(<i>want, claim, wonder, plan...</i>)	Psychological verbs (<i>convince, persuade, dissuade, tempt...</i>)	Communicative verbs (<i>tell, ask, urge, recommend...</i>)
Interpretation of PRO	Obligatory <i>de se</i>		Obligatory <i>de te</i>

While *de se* refers to the attitude holder's identification of himself or herself for whom they are, *de te* refers to the attitude holder's identification of the addressee(s) for whom they are. The two senses are obviously related (and should receive a unified explanation), but the class of object control verbs splits between them, as originally noted by Chierchia (1990). Under an object experiencer verb, PRO is understood *de se* with respect to the matrix object's perspective. Suppose Mary listens with John to a recording of a speech. The speaker in the recording is John himself, although he is not aware of that. After a while, Mary feels she has had enough and wants to put an end to it. (36a), which allows a *de re* reading, is a possible description of her actions, but (36b) is not, being obligatory *de se*. The latter really implies something like the paraphrase in (36c).

- (36) a. Mary persuaded John_i that he_i should shut up.
b. Mary persuaded John to shut up.

- c. Mary caused John to entertain the desire: “I should shut up”.

Consider now a verb of communication like *tell*, with the same scenario, only this time it is Mary who does not recognize the speaker of the recorded speech as the person standing next to her, John. Then we can describe her actions with (37a), in which *he* is read *de re*, but not with (37b), where PRO is obligatorily read *de te*. The latter must be paraphrased along the lines of (37c).

- (37) a. Mary told John_i that he_i should shut up.
- b. Mary told John to shut up.
- c. Mary told John: “You should shut up”.

Looking at table (35) from a θ -theoretic perspective, we can say that *de se* is triggered by Agent and Experiencer controllers and *de te* by Goal controllers. The semantic feature implicated in the former two and not in the latter is the presence of a mental state; in Reinhart's (2002) terms, *de se* is linked to $[/+m]$ clusters. From the logophoric perspective, this natural class is defined by the AUTHOR coordinate of the embedded context: The matrix participant whose mental perspective is reported.³¹

Interestingly, in *de te* attitudes the link between the AUTHOR coordinate and control breaks. Quite clearly, goal controllers need not entertain any mental state or attitude with respect to the embedded event. Furthermore, contrary to Stephenson's (2010) claim, it is not necessary that the agent intend for the goal to entertain an intention to perform the requested action. Because complements of object control always denote actions, and actions are intentional (see Jackendoff & Culicover 2003), the common interpretation of object control would indeed involve an intention on the part of the matrix object. But this is a fact about actions and not about the tacit intentions of the matrix agent, who simply wants an action performed.

- (38) a. Mary ordered John to stay home even if he doesn't want to.
- b. In meditation, the most dramatic results are achieved when you let go of your desires and intentions. When they reach this state, I tell my students to start the exercise.

What *de te* attitudes teach us, then, is that OC PRO (in attitude contexts) is not necessarily linked to the *de se* “center” in the world of evaluation - the attitude holder - as maintained in the centered-world approach (Stephenson 2010). The attitude holder *is* implicated, in fact, in fixing the worlds of evaluation, but need not be the controller. This in no way implies that PRO is ambiguous. Rather, there is a choice as to whether PRO is

³¹ I therefore find Stephenson's (2010) argument against a context-shifting account of object control unconvincing. Stephenson points out that object control verbs like *persuade* may take an inanimate subject (Cause), in which case there is neither a speech event nor an ADDRESSEE role to bind PRO. But object experiencer verbs do not denote speech events to begin with; on their canonical use, they denote psychological events, and the controller is the experiencer, precisely because it binds the AUTHOR coordinate. Possibly, it is on their marked use, as verbs of communication, that control may shift to the subject; see (80) below. This is not to say that the context-shifting approach to OC is without problems; see the next section for discussion.

bound by the AUTHOR or the ADDRESSEE coordinate of the context of evaluation. This is the path we will take below. Nevertheless, since the bulk of the semantic work concentrates on explicating *de se* attitudes, the theoretical terrain is defined by the various ways this particular interpretation arises.

Building on the insights of the extensive work cited in fn. 30, I adopt two background assumptions, one about the syntax of attitude complements and one about their semantics. Syntactically, attitude verbs select clausal complements whose left periphery represents the context of speech (or thought) of the matrix event, also called “the context of evaluation”. This context is a tuple consisting of (at least) four coordinates: <author, addressee, time, world>; to use Bianchi’s apt term, the “logophoric center” of the clause. This information resides in the C head of the clause and may affect the interpretation of any context-sensitive element under the scope of C.³² In section 3.4.4 I will actually suggest that the descriptive predicates AUTHOR and ADDRESSEE are not built into the context tuple but rather are introduced as presuppositional properties of the first two coordinates, which are simple variables, bound by the author and addressee of the matrix event. These variables may be projected as syntactic elements and carry nominal features (see below).

Semantically, the coordinates of the context of evaluation represent the way the attitude holder “locates” himself, his addressee and the event time in the situations that express (conform to) his beliefs or desires. Thus, these are all *de se* (or *de te*) coordinates, although we will shortly see that there is more than one way in which the *de se* reading may arise.

Current research assumes that attitude verbs are intensional quantifiers but splits on the question of what they quantify over, and correlatively, what is the semantic type of their complements. One school of thought takes attitude complements to denote sets of contexts (Schlenker 2003, 2011, Anand & Nevins 2004, Anand 2006), whereas a second one takes them to denote properties or centered-worlds (Chierchia 1990, Stephenson 2010, Pearson 2013). Within this space, there are three “paths to *de se*” in OC (see Anand 2006 for discussion).

(39) Paths to *de se* in OC

- a. PRO is a shifted indexical.
- b. PRO is locally bound by an operator (on a par with logophoric pronouns).
- c. PRO triggers a special *de re* interpretation, which amounts to *de se*.

Path (39a) is represented in Anand and Nevins 2004, but the core intuition is already formulated in the appendix to Postal 1970 (see also Kuno 1972). As mentioned, it is also implicated in Schlenker’s 2003 solution to the problem of forcing a *de se* presupposition in OC, and it seems to be lurking in Baker’s (2008:131) analogy between English OC and

³² This is different from Bianchi (2003), who locates the logophoric center in Fin⁰. Since predicative (non-attitude) complements also project up to FinP, we cannot follow Bianchi on this point. Notice that the addressee coordinate is only present under verbs of communication (e.g., *want* and *think* introduce contexts without it). I also leave out the LOCATION coordinate.

indexical shift in Slave.³³ A formal representation of this analysis is given below, illustrated with the OC verb *intend*. Notice that the set of evaluated contexts in (40d) is selected in such a way that the author in each of them is the *de se* counterpart of the matrix subject.³⁴

(40) *Semantics for OC verbs by indexical shift*

- a. $\llbracket [PRO \text{ to } VP] \rrbracket^{g,c,w} = \lambda c'. \llbracket VP \rrbracket^{g,c}(\text{AUTHOR}(c'))(c')$
- b. $\llbracket intend \rrbracket^{g,c,w} = \lambda p. \lambda x. \lambda c'. \forall i' \in \text{INTEND}_{x,w}, p(i')=1$
- c. $\llbracket intend [PRO \text{ to } VP] \rrbracket^{g,c,w} = \lambda x. \lambda c'. \forall i' \in \text{INTEND}_{x,w}, \llbracket VP \rrbracket^{g,c}(\text{AUTHOR}(i'))(i')=1$
- d. $\text{INTEND}_{x,w}$ = the set of contexts compatible with x's intentions in w.

We discuss and eventually reject this analysis in the next section.

Path (39b) is represented in Chierchia 1990, von Stechow 2003, Anand 2006, Schlenker 2011 and Pearson 2013; it amounts to treating PRO as a logophor with the special property of being necessarily bound by the most local operator. The following representation is adapted from Pearson 2013. Once again, notice how the *de se* reading is guaranteed by the way the set of individual-time-world tuples is selected, (41d).

(41) *Semantics for OC verbs by local operator binding*

- a. $\llbracket [PRO \text{ to } VP] \rrbracket^{g,c} = \lambda z. \lambda t'. \lambda w'. \llbracket VP \rrbracket^{g,c}(z)(t')(w')$
- b. $\llbracket intend \rrbracket^{g,c} = \lambda P. \lambda x. \lambda t. \lambda w. \forall \langle w', t', y \rangle \in \text{INTEND}_{x,t,w},$
 $\exists t'': t' <_{\text{precedes}} t'' \ \& \ P(y)(t'')(w')$
- c. $\llbracket intend [PRO \text{ to } VP] \rrbracket^{g,c} = \lambda x. \lambda t. \lambda w. \forall \langle w', t', y \rangle \in \text{INTEND}_{x,t,w},$
 $\exists t'': t' <_{\text{precedes}} t'' \ \& \ \llbracket VP \rrbracket^{g,c}(y)(t'')(w')$
- d. $\text{INTEND}_{x,t,w} = \{ \langle x, t, w \rangle \mid \text{it is compatible with } x \text{'s intentions in } w \text{ at } t \text{ for } x \text{ to be } y \text{ and for } t \text{ to be } t' \}$

We discuss the shortcomings of this line of research in section 3.4.3.

Path (41c) is represented in Schlenker 2003 and Maier 2011. As the philosophical literature on *de re* attitudes makes clear, the range of *de re* ascriptions is very broad, the only constraint being that the description of the *res* must stand in some “acquaintance relation” to the attitude holder. In this context, it is possible to view *de se* as that special case of *de re* where the acquaintance relation that holds between the attitude holder and the *res* is identity (“This person is me!”). Crucially, on this analysis only, but not on the

³³ Since Baker proposes that 1st/2nd person pronouns are *always* locally bound by an operator, his theory is a blend of (39a) and (39b).

³⁴ The following notation is used: *c* (*c'*, etc.) is a context variable whose semantic type is κ (a tuple of coordinates). *c** designates the (matrix) utterance context and *i'* designates the (embedded) speech/thought context of evaluation (sometimes called ‘index’). *t* (*t'*, etc.) is a temporal interval variable and *w* (*w'*, etc.) is a world variable. Individual variables, *x* and *y*, are of type *e*, and truth values {0,1} are of type *t*. Propositional variables *p* are of type $\langle \kappa, t \rangle$, property variables *P* are of type $\langle e, \langle s, t \rangle \rangle$. *g* is the assignment function.

other two analyses, PRO is directly bound by the controller. This difference will play an important role in the explanation of the OC-NC generalization (section 3.5).

The "special *de re*" analysis, however, faces difficulties with obligatory *de se* elements, like PRO in attitude contexts. The standard procedure is to attach a lexical presupposition to the *de se* element, to the effect that the only accessible acquaintance relation is the identity relation. This is carried out by a shifted indexical feature in Schlenker 2003 (effectively blending (39b) and (39c)) and by a pragmatically-interpreted feature in Maier 2011. Neither solution is compatible with the principal constraint of the present study - namely, the analysis of PRO as a minimal pronoun (see section 3.2), and both would need to multiply the lexical entries for PRO in other environments. The problem, however, may be merely implementational: Perhaps PRO in attitude contexts is the same minimal pronoun, and the *de se* presupposition is introduced by a distinct element in the structure. This is the path we will explore in section 3.4.4.

3.4.2 OC PRO is not a shifted indexical

To start from Postal's (1970) original insight, control complements represent indirect discourse (ID) reporting direct discourse (DD) events. When the "underlying" direct discourse sentence is recovered, we observe the emergence of a personal pronoun as its subject.

- (42) a. Harry told Betty to marry him / (You) marry me, Harry told Betty.
 b. Harry asked Betty to marry him / Will you (please) marry me, Harry asked Betty.
 c. Harry promised Betty to leave / I will leave, Harry promised Mary.
 d. Harry asked Betty when to leave / When should I leave, Harry asked Betty.

Postal stated the generalization: If the DD subject is 2nd person, the ID subject (PRO) is object-controlled; if the DD subject is 1st person, the ID subject is subject-controlled. Note that the semantics of personal pronouns guarantees the correct *de se* and *de te* interpretations, if DD does underlie ID.

As it turns out, certain environments in certain languages wear their DD complements on their sleeves; a 1st person pronoun in a complement of an attitude verb refers not to the speaker but to the attitude holder (often the matrix subject), and a 2nd person pronoun in the complement refers to the addressee of the attitude (the matrix object). An example from Zazaki is given below (Anand & Nevins 2004); note that the embedded subject may refer either to the speaker (index *k*) or to *Hesen* (index *j*).³⁵

³⁵ Shifted indexicals have been documented in Slave (Rice 1989), Navajo (Speas 2000), Amharic (Schlenker 2003, Anand 2006), Zazaki (Anand & Nevins 2004, Anand 2006), Catalan Sign Language (Quer 2005), Matsigenka (Ludwig et al. 2010), Turkish (Gültekin-Şener and Şener 2011), Uyghur (Shklovsky & Sudo, to appear) and Nez Perce (Deal 2013).

- (43) Hesen_i (mi-ra) va kε εZ_{j/k} dɛwletia.
 Hesēn.OBL (I.OBL-to) said that I rich.BE.PRES
 ‘Hesen said that {I am, Hesen is} rich.’

The formal analysis of this phenomenon involves overwriting the *context* parameter of evaluation (a tuple consisting of the world, time, location, author and addressee of the utterance context) with the *index* parameter (a similar tuple corresponding to the attitude context). Thus, within the worlds of evaluation for the complement in (43) - all the worlds consistent with what Hesen says - the first person pronoun refers to the “author” of the world, namely, to Hesen. Indexical shift is a shift in the context of evaluation, triggered by specific verbs (or pronouns, see below).

Anand & Nevins suggest that OC PRO should be simply identified with a shifted indexical, as follows (*c* - the constant context of evaluation; *i* - the current, shiftable context of evaluation).

- (44) a. $[[\text{PRO}_{\text{subj}}]]^{c,i} = \text{AUTHOR}(i)$ *subject-controlled PRO*
 b. $[[\text{PRO}_{\text{obj}}]]^{c,i} = \text{ADDRESSEE}(i)$ *object-controlled PRO*

The proposal to be developed in section 3.4.4 will end up semantically equivalent to indexical shift. Crucially, however, it will not make use of the idea that PRO is an indexical pronoun. There are, in fact, serious objections to this idea.

The first, possibly minor objection, is that on the shifted indexical theory, one must posit two entries for OC PRO, (44a) and (44b), just like one must distinguish the lexical entries of *I* and *you*. Together with non-indexical PRO (used in predicative, non-attitude contexts), this makes for three types of PRO - three times as many as needed on the minimal pronoun approach.

The second objection concerns crosslinguistic distribution. The phenomenon of shifted indexicals is rather uncommon to date has been documented around 10 languages (see fn. 35). Moreover, in most of them, indexical shift is restricted to the complement of a single verb, ‘say’, or possibly 3-4 verbs. In Slave, it is found with ‘say’, ‘tell’ and two versions of ‘think/want’; and in Navajo it is found with ‘say’ for all speakers and dialectically with ‘think’ and ‘want’. Whatever one’s favorite mechanism of deriving shifted indexicals, it better be a highly marked one.

But then one wonders - what makes this mechanism completely mundane in the realm of control, available in most languages of the world, and for dozens of verbs in each language? In fact, none of the complement clauses in which genuine indexical shift has been documented displays OC; they are all uncontrolled complements. These asymmetries are puzzling if PRO is just another type of shifted indexical, albeit an unpronounced one.³⁶

³⁶ Anand (2006:93) makes a similar point.

The third objection concerns selectivity and optionality. Even within the small data set of shifted indexicals documented in the literature, there is a great deal of variation. In Slave, 1st person pronouns obligatorily shift under ‘say’ but only optionally shift under ‘want’; 2nd person pronouns do not shift under these verbs. On the other hand, both 1st and 2nd person pronouns optionally shift under ‘tell’. The latter pattern is also exhibited by ‘say’ in Amharic and Navajo. In Zazaki, shifting is optional too (under ‘say’) but it is unselective (all indexicals may shift).

The literature accounts for this variation by assuming that the presence of context shifting operators in the complement clause is regulated by largely idiosyncratic selectional specifications (Anand 2006, Baker 2008, Schlenker 2011). Turning to OC, however, we witness striking systematicity: All verbs with agent/experiencer controller, we would have to assume, induce obligatory shift of the 1st person PRO, and all verbs with goal controllers induce obligatory shift of the 2nd person PRO (see table (35)). Appropriate selectional specifications can no doubt be tailored for OC complements, but this would beg the question of what makes indexical shift so systematic in OC but not elsewhere.

The fourth and final objection concerns simple morphological facts. Genuine shifted indexicals preserve their “direct discourse” [person] value; thus, the embedded subject in (43) is specified [person:1st]. OC PRO, in contrast, inherits its [person] value from the controller, regardless of its interpretation as a “shifted” indexical. This can be observed on agreeing reflexives.

- (45) a. John planned [PRO to promote himself / *myself]
- b. John planned: “I will promote myself”.

This mismatch between the form and semantic value of OC PRO in attitude contexts is a well-recognized problem (see the extensive discussion in Schlenker 2003), but it is particularly thorny for the shifted indexical theory, since on this theory, PRO is *inherently specified* as the context’s author or addressee, just like the pronouns *I* and *you* are. To reconcile these facts, one would have to maintain that only in the case of shifted indexicals (but not in unshifted ones), [person] features are semantically interpreted but morphologically unspecified, and a separate process of agreement (with the controller) guarantees their morphological valuation. This is possible in principle, but surely less appealing than the null hypothesis, whereby PRO is inherently unspecified *both* semantically and morphologically.

To summarize this section: there are compelling theoretical and empirical reasons to reject solution (39a) to the obligatory *de se* interpretation of OC PRO (in attitude complements). We next turn to consider solution (39b), local binding by an operator.

3.4.3 OC PRO is not a logophoric pronoun

The term logophoric control naturally brings to mind the familiar phenomenon of logophoric pronouns (LPs), studied extensively in African languages, and occasionally extended to cover long-distance reflexives as well (see Culy 1994 and Reuland 2006 for

useful surveys). Indeed, there are two obvious similarities between PRO in attitude contexts and LPs: (i) both occur only in attitude complements, and (ii) both are bound by participants of the speech/thought event. The examples below are from Edo (Baker 2008:135) and Ewe (Clements 1975); notice that the embedded logophoric pronouns are obligatorily coindexed with their matrix antecedents, which, in turn, determine the AUTHOR coordinate of the embedded context.

- (46) a. Òzò miàmián wẹẹ írèn kìé èkhù. *Edo*
 Ozo forgot that he.LOG opened door
 ‘Ozo_i forgot that he_{i/*k} opened the door.’
- b. Me-se tso Kofi gbɔ be yè-xɔ nuana. *Ewe*
 I-hear from Kofi side that he.LOG-receive gift
 ‘I heard from Kofi_i that he_{i/*k} received a gift.’

There is strong evidence that LPs are licensed by operators located at the CP-periphery (Koopman & Sportiche 1989, Safir 2004, Adesola 2005, Baker 2008, Anand 2006). It is therefore not implausible to suggest that OC PRO is a special kind of a logophoric pronoun (von Stechow 2003, Anand 2006). There are, however, problems with this assimilation, both within the present framework and independently of it, similar in nature to the problems with the analysis of OC PRO as a shifted indexical.

First, in terms of distribution, LPs are found in complements of declarative and cognitive verbs but *never inside OC complements* (Culy 1994). This absence of overlap is puzzling on the view that the same operator that licenses LPs licenses OC PRO.

Second, logophoric domains are often optional. Although certain languages employ designated complementizers that force the use of LPs in their scope (if reference to a matrix argument is desired), the more common pattern is for attitude complements to display optional logophoricity effects. Of course, this is unlike OC PRO (under attitude verbs), which is obligatorily anchored to the embedded context.

Third, among the potential antecedents for LPs (in various languages) is the discourse role SOURCE (see Sells 1987), as in (46b), but to the best of my knowledge, this role is never assumed by OC controllers.

Fourth, whereas OC PRO must be bound by the most local operator, LPs need not be locally bound and in fact may pick as their binder any c-commanding complementizer (capable of licensing LPs), however distant it is. Moreover, clausemate LPs need not be bound by the same operator.

Fifth, LPs are not restricted to subject position, but PRO is.

Sixth, just as with the indexical shift theory of OC, the mechanism of agreement between PRO and the controller is unclear. While PRO must inherit the ϕ -features of its local binder – the individual abstractor located in the embedded C – owing to the binding

relation (Heim 2008, Kratzer 2009; see (66) below), how is the latter guaranteed to inherit the ϕ -features of the matrix controller? Crucially, no *syntactic* relation is established between the variable y and the abstractor λx in the formula (41c); they are only linked by the "*de se* counterpart" relation in the lexical semantics of the control verb. While it is customary in the semantic literature to take that as sufficient grounds for morphological agreement (see, e.g., von Stechow 2003), the causal relation is stipulated, not explained by any known syntactic or morphological procedure.³⁷

All these considerations suggest that analyzing PRO as a locally bound pronoun (possibly with a [log] feature) would still leave us far behind the goal of explaining its properties and distribution. From the present perspective of attempting to unify all the manifestations of OC PRO, this analysis would also be unappealing for an independent reason: It cannot extend to predicative control (where no logophoric effects exist), and hence would be forced to posit two types of PRO, failing to meet the minimal pronoun desideratum. Although the investigation of LPs holds many important insights for the analysis of logophoric control, the latter cannot be reduced to the former.³⁸

3.4.4 The proposal: binding a coordinate of C

Having considered and dismissed two types of analyses - PRO is a shifted indexical or a logophoric pronoun - we are in a position to present the present proposal: PRO is a variable bound by the matrix controller which is associated with a special *de re* description (the "authorship" relation). This section lays out the formal syntactic and semantic ingredients of this analysis.³⁹ The morphological aspects are subsequently discussed in section 3.5, where a novel, independent argument for favoring this proposal over its alternatives will come to light.

Recall that on the view of attitude verbs as quantifiers over sets of contexts, a context is taken to be a tuple of coordinates, which are nothing but variables, each associated with its own indexical descriptive content: $i = \langle \text{AUTHOR}(i), \text{ADDRESSEE}(i), \text{TIME}(i), \text{WORLD}(i) \rangle$. We may think of the coordinates of i (the embedded context) as *arguments* of C (the complementizer). While these arguments are normally not present in the syntax (being implicit, so to speak), they may project syntactically under certain circumstances. This is the fate of the AUTHOR (or ADDRESSEE) coordinate in OC.

³⁷ See, for example, Pearson 2013:145, where an agreement relation is superimposed on the semantic relation between the attitude verb and whichever of its arguments identifies the doxastic alternatives it quantifies over, piggybacking the feature [att]; the embedded operator then "agrees" with the attitude verb and acquires the necessary ϕ -features. These agreement mechanisms are not otherwise attested and are *never* reflected in the morphological shape of the attitude verb. Additional stipulations would be necessary to make oblique controllers – otherwise systematically inert for agreement – visible only to this particular process. Note that I assume that agreement must be defined over *some* syntactic relation, having no direct access to semantic representations. Dropping this assumption has severe repercussions for the modular architecture of the grammar that do not seem warranted otherwise.

³⁸ Logophoric pronouns have been claimed to generate obligatory *de se* readings (Schlenker 2003, 2011, Anand 2006), which would further distinguish them from OC PRO (see (24), (25c-d), (26)). Recently, however, it was discovered that logophoric pronouns in Ewe can be read *de re* (Pearson 2013).

³⁹ I am indebted to Orin Percus for stimulating discussions that sharpened my understanding of the semantic issues.

It is worth noting that nothing forces this particular packaging of the coordinate variables with their respective descriptive contents. Semantically, an equivalent result could be achieved if the context would consist of pure variables, bound by the matrix attitude holder and addressee, with their descriptive content being introduced syntagmatically, so to speak. This is the intuition I will explore below, at least for the individual coordinates, leaving open the question whether the time and world coordinates should be treated the same way. Thus, we take the context introduced by an attitude predicate to be:

$i = \langle x, y, \text{TIME}(i), \text{WORLD}(i) \rangle$. The individual variables x and y are directly bound by the arguments denoting attitude holder and addressee in the matrix clause. Importantly, this binding relation is inherent in the semantics of any attitude verb and is not particular to OC environments. What is special about the OC complementizer (henceforth, C^{OC}) are two properties: (i) syntactically, it must project one of its individual coordinates as a specifier; (ii) semantically, it introduces the "special *de re*" presupposition of an identity acquaintance relation, which amounts to obligatory *de se* reading.

Before we turn to OC as a special case of *de re* ascription, let us outline the general case. The formal implementation below is an adaptation of the proposal in Percus & Sauerland 2003 (see also Pearson 2013: Ch. 7); for discussion of the background philosophical and semantic issues arising with *de re* beliefs, the reader is referred to this work, as well as Schlenker 2003, 2010 and Anand 2006.

On the *de re* analysis, a sentence like *Ralph believes that Orcutt is a spy* is rendered as 'There is a vivid description of Orcutt for Ralph such that under this description, Ralph believes of Orcutt that he is a spy'. The two notable features of this analysis are: (i) the attitude verb selects an additional (syntactically invisible) argument, the so called *res* of the belief; (ii) the acquaintance relation between the attitude holder (AH) and the *res* must be unique and "vivid", which means, in the least, that the AH must consciously associate the description with the *res*. I will follow Anand (2006) in calling this cognitive condition the *suitability condition* on *de re* beliefs. Importantly, the suitability condition implies that an egocentric perspective (of the AH) is built even into standard *de re* beliefs. This will be the key to the "*de se* as a special *de re*" analysis, in which the AH is suitably acquainted with a *res* that happens to be himself.

Following Percus & Sauerland (2003), we will introduce the *unique acquaintance* relation between the AH and the *res* via a concept generator, G , defined below.

- (47) $\llbracket G \rrbracket^{g,c} = \lambda res_e. \lambda i'_{\kappa}. i(r_e)$: r is picked by the description G of the *res* for the AH (=the AH's concept of the *res*) in context i' .

We may think of G as a way of picking the "counterpart" of the *res* in the AH's doxastic alternatives. Note that we treat concept generators as functions from individual-*context* pairs (as in Anand 2006) and not from individual-*world* pairs (as in Percus and Sauerland 2003a), in order to be able to define G s that pick specific coordinates of the context as the description of the *res*. We do follow Percus & Sauerland in assuming that the acquaintance relation must be unique. Given (47), we can define *suitability* as follows.

(48) A concept generator is *suitable* for an attitude-holder x in context c iff:

- a. Acquaintance: $\forall y \in \text{Dom}(G), x$ is acquainted with y in c .
- b. Uniqueness: $\forall y, z \in \text{Dom}(G), y \neq z \rightarrow G(y) \neq G(z)$.

Finally, to capture the fact that *de re* beliefs are relativized to descriptions, the attitude complement is analyzed as a function from concept generators to propositions (the variable Q below). The proposition itself is produced by predicating the embedded property of the "counterpart" of the *res*; below, this embedded property is the denotation of the same FinP used in predicative control, and the *res*-counterpart is introduced as a nominal argument of C , a transitive head just like Fin .

The different pieces are put together in (49)-(50).

(49) de re: the general case

- (50) a. $\llbracket \text{CP} \rrbracket^{g,c} = \lambda i'. \llbracket \text{FinP} \rrbracket^{g,c}(g(7)(\text{res})(i'))(i')$
 b. $\llbracket \text{CP}_Q \rrbracket^{g,c} = \lambda G_7. \lambda i'. \llbracket \text{FinP} \rrbracket^{g,c}(G_7(\text{res})(i'))(i')$
 c. $\llbracket \text{intend} \rrbracket^{g,c} = \lambda Q. \lambda \text{res}. \lambda x. \lambda w. \exists G \text{ for } x \text{ in } w \wedge G \text{ is suitable}$
 $\wedge \forall i' \in \text{INTEND}_{x,w}, Q(G)(i') = 1$
 d. $\llbracket [\text{intend } \text{CP}_Q] \rrbracket^{g,c} = \lambda \text{res}. \lambda x. \lambda w. \exists G \text{ for } x \text{ in } w \wedge G \text{ is suitable}$
 $\wedge \forall i' \in \text{INTEND}_{x,w}, \llbracket \text{FinP} \rrbracket^{g,c}(G(\text{res})(i'))(i') = 1$

For example, *Ralph intended for Betty to join the club* receives the paraphrase: There is a concept generator for Ralph that establishes a suitable acquaintance relation between Ralph and Betty under some description, and in all of the contexts that conform to Ralph's intentions, the person picked by that description joins the club.

Our interest is in reflexive *de re* beliefs, in which $\text{res} = \text{AH}$ (the variable x in (50)).

(51) For $res=AH$ (G is a description of the attitude holder for himself):

$$\begin{aligned} \llbracket [intend CP_Q] \rrbracket^{g,c} &= \lambda x. \lambda w. \exists G \text{ for } x \text{ in } w \wedge G \text{ is suitable} \\ \wedge \forall i' \in INTEND_{x,w}, \llbracket FinP \rrbracket^{g,c}(G(x)(i'))(i') &= 1 \end{aligned}$$

Note that this need not generate a *de se* reading. $G(x)(i')$ could be "the person X sees in the mirror in i ", consistent with a misidentification scenario. To guarantee the *de se* reading, we need to define G_{SELF} . Similarly, for *de te* readings we define G_{THOU} .

- (52) a. $G_{SELF} =_{\text{def}} G: \forall y \in \text{Dom}(G), G(y) = \text{AUTHOR}$
 $\llbracket G_{SELF} \rrbracket^{g,c}(z) = \lambda c'. \text{AUTHOR}(c')$
 b. $G_{THOU} =_{\text{def}} G: \forall y \in \text{Dom}(G), G(y) = \text{ADDRESSEE}$
 $\llbracket G_{THOU} \rrbracket^{g,c}(z) = \lambda c'. \text{ADDRESSEE}(c')$

G_{SELF} and G_{THOU} are constant functions. Because of the uniqueness condition (48b) on suitable G s, their domains are singletons. Thus, every individual is paired with a unique G_{SELF} and a unique G_{THOU} , which map it to the AUTHOR and ADDRESSEE functions, respectively. Focusing on *de se*, it is easy to see that the AUTHOR function yields it. In the general terms of *de re* beliefs, if one of the suitable concept generators for AH is G_{SELF} , then AH is known to himself as the author of his thoughts.

The crucial question is what makes *de se* obligatory in OC contexts. From the present perspective, this translates to the question - what forces the choice of G_{SELF} among all the possible G s? This bit of semantic information cannot be part of the meaning of the attitude verb itself, which, of course, accommodates all kinds of *de re* ascriptions, not just the special case of *de se* (cf. (50)). The natural locus for this information is rather the OC complementizer, C^{OC} ; it is only in combination with this complementizer that attitude verbs generate obligatory *de se* readings. This intuition is cashed out below as a presupposition triggered by C^{OC} .

Syntactically, logophoric OC complements instantiate the general scheme of *de re* complements (49). The predicative $FinP$ is exactly the constituent formed in predicative control (see (31)). To recall, this constituent is a derived predicate formed by PRO movement to $[\text{Spec}, \text{Fin}]$. In logophoric control, it serves as the complement of the complementizer that hosts the logophoric center. In this way the two types of control are strongly integrated; in effect, logophoric control is a logophoric center overlaid, as a second tier, on predicative control, the first tier.⁴⁰

The difference lies in what the predicate is predicated of. Whereas $FinP$ is directly predicated of the matrix controller in predicative control, in logophoric control it is predicated of GP , a function of a projected coordinate of the embedded context. This coordinate is nothing but a *de re* variable bound by the controller and associated with a *de se* interpretation thanks to a " G_{SELF} presupposition" triggered by C^{OC} . Keeping to devices

⁴⁰ The categorial distinction between the two types echoes earlier proposals that control complements are not all the same size and different types project a different amount of functional structure (Rochette 1988, Wurmbrand 2003, to appear, Grano 2012).

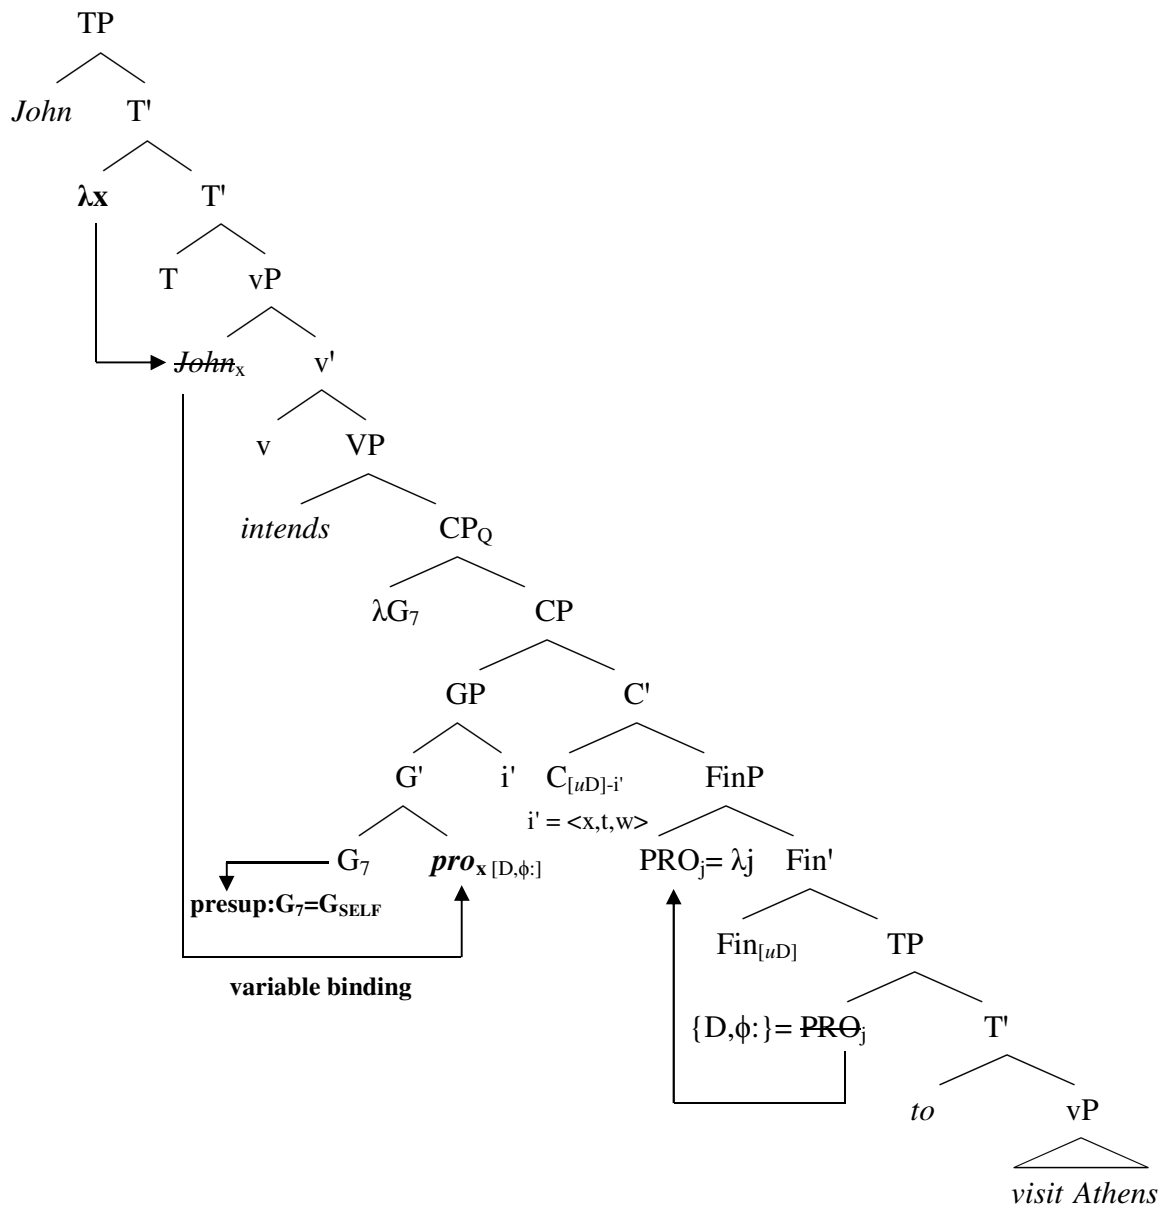

already utilized in the analysis of predicative control, assume that the presence of this syntactic argument in [Spec,CP] is forced by selection. Just like Fin, C^{OC} is a transitive head endowed with a selectional feature [μD]. This feature forces one of the nominal coordinates of the embedded context i' – corresponding to the attitude holder or addressee – to project as the specifier of C, turning the complement into what we might call a "perspectival CP".

On minimal assumptions, this coordinate is nothing but a pure variable, hence, I suggest, is realized as a minimal pronoun too, just like PRO, consisting of the feature bundle [D, ϕ :] (see (27)). We return below to the mechanism by which the ϕ -features of this element are valued. To keep the symbols distinct, I will refer to a projected AUTHOR coordinate as pro_x and to a projected ADDRESSEE coordinate as pro_y .

The central player in logophoric control, then, is C^{OC} , which performs several functions. First, it projects one of its individual coordinate variables as a specifier. Second, it predicates its complement of (a function of) this variable; third, it attaches a G_{SELF} presupposition to this variable; and finally, it abstracts over contexts. Note that of these functions, only the first and the third are specific to C^{OC} , the other two being shared by all complementizers that mediate *de re* attitudes.

The diagram below illustrates the syntactic derivation of a simple attitude subject control sentence; object control with communicative verbs receives a parallel treatment, except that $C_{i'}$ projects pro_y instead of pro_x .

(53) *Derivation of logophoric control*

Several distinctive advantages of this analysis merit comment. First, this analysis sides with Chierchia 1990, Anand 2006, Schlenker 2011 and Pearson 2013, and against Schlenker 2003, von Stechow 2003 and Stephenson 2010, in that the binding relation into which PRO enters is represented *syntactically*; the binder pro_x occupies a position in the syntactic tree and not just in the semantic formulae. There is, in fact, diverse evidence that operators regulating logophoricity, point of view and context shifting are part of syntax, interacting with binding, scope and agreement phenomena (see Koopman and Sportiche 1989, Uriagereka 1995, Bianchi 2003, Safir 2004, Speas 2004, Anand 2006,

Baker 2008, Sundaresan 2012, Shklovsky and Sudo, to appear). In section 3.5 I present a novel argument for the syntactic reality of the local binder of PRO, drawing on its interaction with agreement (the OC-NC generalization).⁴¹

Second, the *de se* component is dissociated from PRO, still a minimal pronoun just as it is in predicative control. This adequately captures the crosslinguistic observation that obligatory *de se* is a *constructional* property of attitude OC complements and not an exclusive feature of PRO. Thus, controlled lexical pronouns in Korean (Madigan 2008b) and Hungarian (Szabolcsi 2009) exhibit this property just like PRO does in the same environments (I return in section 5 to controlled pronouns). Conversely, PRO fails to exhibit it in non-attitude contexts (cf. (24), (25c-d), (26)). The property only arises in attitude OC complements because it is specifically written into the lexical entry of their head, C^{OC}. It arises as a presupposition attached to an argument of the head, just like run-of-the-mill lexical presuppositions do.

Third, note that the effect of the transitivity of C - its selectional feature [*uD*] - is to force control by *one* of the two individual coordinates (author or addressee) without specifying which (setting aside split control; see section 5). Another way of putting it is that the "control module" – the procedure for selecting a matrix controller – is not part of the LF of logophoric control structures. This neutrality is a virtue, because it is well known that control may shift from the matrix subject to object and vice versa, under complex semantic and pragmatic conditions (see section 4.3). The current division of labor correctly situates the negotiation between the two options in post-LF interpretive processes.

Fourth, the analysis derives in a principled way a property of OC that used to baffle semanticists: The fact that PRO (or the context variable associated with it) is necessarily bound by the most local operator (Chierchia 1990, von Stechow 2003, Anand 2006, Schlenker 2011). Within the semantic approaches, this locality is achieved by brute force: "tagging" PRO and its binder with the same diacritic or imposing some ad-hoc condition on its context variable. Nothing of that sort is needed on the analysis in (53). PRO is locally bound by *pro_x* (itself a variable, not an operator) because the former creates the predicate that applies to the latter. Furthermore, the context variable to which the G_{SELF} function applies must be the local *i*' (and not, say, the matrix *c**) because the function is *introduced* by C_{*i*}.⁴²

⁴¹ At the same time, we avoid the false prediction that PRO should invariantly display indexical person features, as on the shifted indexical theory (see section 3.4.2). The indexical function AUTHOR (or ADDRESSEE) is not represented syntactically in structures like (53) but only participates indirectly in the semantic computation (via the *de se/de te* presupposition).

⁴² One technical question that may arise in connection with the derivation in (53) is why PRO cannot satisfy the [*uD*] feature on C by moving yet one further step, making superfluous the external merge of the minimal pronoun *pro_x*. Note that this would amount to movement into a thematic position, [Spec,CP] being an argumental position selected by C. Even if such movements are allowed, the concomitant semantics would have to change, with potentially negative consequences. Thus, it is no longer clear that on such a derivation the predicate would be formed at the level of FinP and not higher up, breaking the analytic linkage to predicative control.

Fifth and finally, the explanation for the subjecthood of PRO and the ban on lexical subjects in predicative control readily carries over to the present case of logophoric control. pro_x binds the open position in the predicative FinP which, as discussed in the section 3.3, must be the subject position (due to locality). And a lexical DP instead of or in addition to PRO would produce a proposition (see (32)) that would fail to combine with pro_x via predication.

At this point we can provide an explicit compositional semantics for logophoric OC, on the basis of the lexical entry for *intend* in (50c) and the structure in (53).

(54) *Semantic composition of logophoric control*

- a. $\llbracket [\text{FinP PRO to visit Athens}] \rrbracket^{g,c} = \lambda z. \lambda c'. \llbracket \text{visit Athens} \rrbracket^{g,c}(z)(c')$
- b. $\llbracket C_i^{\text{OC}} \rrbracket^{g,c} = G_7 = G_{\text{SELF}} : \lambda P. \lambda y. \lambda i'. P(y)(i') = 1$
- c. $\llbracket C' \rrbracket^{g,c} = \llbracket C_i^{\text{OC}} \rrbracket^{g,c}(\llbracket \text{FinP} \rrbracket^{g,c}) = \lambda y. \lambda i'. G_7 = G_{\text{SELF}} : \llbracket \text{visit Athens} \rrbracket^{g,c}(y)(i') = 1$
- d. $\llbracket \text{GP} \rrbracket^{g,c} = g_7(g(x))(i')$
- e. $\llbracket \text{CP} \rrbracket^{g,c} = \llbracket C' \rrbracket^{g,c}(\llbracket \text{GP} \rrbracket^{g,c}) = \lambda i'. G_7 = G_{\text{SELF}} : \llbracket \text{visit Athens} \rrbracket^{g,c}(g_7(g(x))(i'))(i') = 1 = \lambda i'. G_7 = G_{\text{SELF}} : \llbracket \text{visit Athens} \rrbracket^{g,c}(G_{\text{SELF}}(g(x))(i'))(i') = 1$
- f. $\llbracket \text{CP}_Q \rrbracket^{g,c} = \lambda G_7. \llbracket \text{CP} \rrbracket^{g,c} = \lambda G_7. \lambda i'. G_7 = G_{\text{SELF}} : \llbracket \text{visit Athens} \rrbracket^{g,c}(G_{\text{SELF}}(g(x))(i'))(i') = 1$
- g. $\llbracket \text{intend} \rrbracket^{g,c} = \lambda Q. \lambda x. \lambda w. \exists G \text{ for } x \text{ in } w \wedge G \text{ is suitable} \wedge \forall i' \in \text{INTEND}_{x,w}, Q(G)(i') = 1$
- h. $\llbracket [\text{intend CP}_Q] \rrbracket^{g,c} = \lambda x. \lambda w. G = G_{\text{SELF}} : \exists G \text{ for } x \text{ in } w \wedge G \text{ is suitable} \wedge \forall i' \in \text{INTEND}_{x,w}, \llbracket \text{visit Athens} \rrbracket^{g,c}(G_{\text{SELF}}(g(x))(i'))(i') = 1$

The existential quantification over G is superfluous, given that its value is fixed as G_{SELF} , yielding (54i). Since there is always a suitable choice of G_{SELF} , this is simplified as (54j); and since G_{SELF} maps its argument to AUTHOR , we obtain (54k).

- (54) i. $= \lambda x. \lambda w. G_{\text{SELF}} \text{ is suitable} \wedge \forall i' \in \text{INTEND}_{x,w}, \llbracket \text{visit Athens} \rrbracket^{g,c}(G_{\text{SELF}}(g(x))(i'))(i') = 1$
- j. $= \lambda x. \lambda w. \forall i' \in \text{INTEND}_{x,w}, \llbracket \text{visit Athens} \rrbracket^{g,c}(G_{\text{SELF}}(g(x))(i'))(i') = 1$
- k. $= \lambda x. \lambda w. \forall i' \in \text{INTEND}_{x,w}, \llbracket \text{visit Athens} \rrbracket^{g,c}(\text{AUTHOR}(i'))(i') = 1$

(54k) adequately captures the obligatory *de se* reading of logophoric OC (compare (40c)).⁴³ Consider an AH who is the *de-se*-violating amnesiac. The *res*=AH, who performs the embedded action, does *not* fall under the description “author of my thoughts”. And so there would be contexts i' in which $\text{AUTHOR}(i')$, the person AH takes himself to be in i' , does not visit Athens. This would make the sentence false, as desired.

⁴³ While (54k) boils down to the semantics of shifted indexicals in (40c), the two analyses crucially differ in their morphosyntax. On the indexical shift theory, PRO is *intrinsically* specified [person:1] (which is evaluated w.r.t. the embedded context). This syntactic feature is necessarily visible to PF, falsely predicting 1st person morphology (**John hopes to promote myself*). The “special *de re*” theory avoids this problem by taking PRO (and its proxy pro_x) to be a minimal pronoun variable, *unvalued* for [person]. This variable receives its morphological shape at PF, as detailed in the next section, and its semantic value ($\text{AUTHOR}(i')$) at LF – two mutually inaccessible modules. Thus, no clash arises.

Left to be explained is the mechanism by which PRO comes to agree in ϕ -features with the controller. We turn to it next.

The same syntactic structures that support predicative and logophoric control also support the agreement relations manifested in these constructions. In this section we lay out the mechanisms of agreement involved in both situations. Understanding these mechanisms will pave the way to understanding why they interact differently with morphological inflection in the controlled clause (the OC-NC generalization), the topic of the next section.

the-child-PL.M happy-PL.M

dependent agreement

Classical GB-style Spec-head agreement is capable of yielding agreement in these two cases. Alternatively, they may be handled by the more current operation Agree, which transmits ϕ -values from valued to unvalued occurrences of features. The choice between these options is not crucial for the present concerns.

45

Let us see now how this type of agreement is instantiated in predicative control. To recall, a FinP projection is turned into a predicate by the movement of an operator PRO to its specifier. This predicate then applies to the controller DP via some predicative head (*Rel* or light *v*). Agreement thus piggybacks two syntactic dependencies here: movement and predication.

(56) *φ-agreement in predicative control*

The operator PRO is generated as a minimal pronoun; its [φ:] bundle is valued by the saturating DP controller, *John*. This step could be the result of a direct Agree (*John*, PRO) operation, or an indirect result of a prior Agree (*John*, Fin) operation. Either way, the phase-edge position of the raised PRO and Fin guarantees the locality and the success of this step (Bobaljik and Wurmbrand 2005). The φ-values transmitted to the raised PRO are shared by its lower copy, the variable PRO, by virtue of the movement chain (on feature sharing, see Pesetsky and Torrego 2007).

Consider now how agreement works in logophoric control. To recall, FinP is embedded under a perspectival CP that encodes the matrix participants. The head of this CP projects a pronominal variable, which simultaneously saturates the FinP predicate and is bound by the matrix controller. Thus, agreement travels along three syntactic dependencies: variable binding, predication and movement.

(57) *φ-agreement in logophoric control*

The added component in (57), compared to (56), is variable binding. That variable binding serves as a vehicle for feature transmission has been forcefully argued by Heim (2008) and Kratzer (2009). In particular, even person features become semantically vacuous in contexts of variable binding and lose their indexical presuppositions. The examples below support a sloppy reading in which the pronoun *my* is interpreted as a (possessive) variable ranging over all the individuals in the comparison set and not just over the speaker.

- (58) a. Only I did my homework.
 b. I am the only one who takes care of my children.

Agreement under variable binding trumps semantically coherent alternatives. A reflexive bound by a 3rd person DP that happens to refer to the speaker must agree with its

grammatical (and not the notional) binder (59a);⁴⁵ a bound pronoun that picks a single individual must nevertheless be plural if its binder is so (59b-c).

- (59a) a. Nina respects herself / *myself (uttered by Nina).
 b. They_i all think **they** are the smartest linguist in the room.
 c. * They_i all think **he**_i is the smartest linguist in the room.

Both Heim and Kratzer propose that bound variables inherit their ϕ -features from their binders *at PF*. Because those features are not present in the syntax - rather, only a minimal pronoun is - they are not visible to semantic interpretation. This PF view of agreement has interesting consequences for partial control as well, which I explore in Landau 2013a.⁴⁶

So far, then, we have seen that the proposed analysis of predicative and logophoric control, motivated on syntactic and semantic grounds, accounts rather smoothly for the fact that PRO agrees with the controller. The fact that we need only appeal to mechanisms of agreement already established independently of control is encouraging.

There is, however, one difference between the working of agreement in predication and its working in variable binding, which proves crucial for what follows. The difference is stated below.

(60) *Agreement in predication and variable binding*

- a. The formation of a predication relation is *not* contingent on feature transmission between the subject and predicate.
 b. The formation of a variable binding relation *is* contingent on feature transmission to the pronominal variable.

Beginning with (60a), notice that predication is closely related with agreement only with verbal and adjectival predicates. PP predicates bear no ϕ -features and nominal predicates need not match their subjects in ϕ -features.

- (61) a. John is [_{PP} out of his mind].
 b. Those women_[PL.F] are [_{DP} a committee]_[SG.N].

⁴⁵ We put aside the special behavior of “imposters”, where such mismatches are licensed precisely because the binder contains a covert indexical pronoun (Postal and Collins 2012).

⁴⁶ For semantically-based alternatives, see Rullman 2008, Spathas 2010, Jacobson 2012, Sudo 2013 and Sauerland, to appear. I will not try to compare the consequences of the two approaches here, though the focus-oriented proposals of Spathas and Jacobson obviously do not extend to focus-free constructions.

Heim’s and Kratzer’s proposals differ in two respects: (i) For Heim, feature transmission is unbounded, whereas for Kratzer it is phase-bound; (ii) For Heim, the binder is a nominal expression whereas for Kratzer it is a functional head. Since variable binding in (57) is phase-bound, difference (i) is immaterial in the present context. As for difference (ii), I follow Heim in view of the existence of oblique and PP-internal controllers, whose ϕ -features are not registered on any functional head (this was the final disadvantage of the Agree model listed in section 2.3). More fundamentally, I depart from Kratzer’s suggestion that the λ -abstractor that binds PRO is located in the embedded C, for reasons that will become clear in the next section.

Baker (2008) argues that nominal predications never involve syntactic agreement; both the subject and predicate are generated with independent features and apparent matching effects are solely the result of semantic consistency.⁴⁷ We may concur with Baker that nominal predicates are inherently specified for ϕ -features while still allowing a process of independent agreement to apply, if possible, and under restricted conditions (cf. (55)).

(62) These women_[PL.F] are actresses_[PL.F].

Importantly, (62) involves feature *matching*, not feature transmission. Feature matching between an independently valued predicative head and its subject is also assumed by Kratzer (2009) in the analysis of examples like (58b). That predication as such does not depend on feature transmission can even be seen with adjectival predicates that fail to agree with their subjects. Such is the well-known case of Icelandic quirky constructions.

(63) Henni er kalt/*köld /*kaldri. (Sigurðsson 2008)
 she.DAT is cold.NOM.NEUT.SG /*NOM.F.SG /*DAT.F.SG
 ‘She is cold.’

What emerges from these observations is that the formation of the predicative relation itself is not contingent on feature transmission. Rather, once the relation is formed, morphological processes – drawing on language-particular resources – operate to determine if and to what extent it will be translated into actual morphological agreement between the subject and the predicate. This state of affairs is captured nicely on the view that subject-predicate agreement (just like feature transmission under variable binding) occurs at the PF branch of the grammar, namely, in syntactic configurations that are both visible and sensitive to morpho-phonological processes but not to semantic interpretation (for a defense of this idea, see Sigurðsson 2006, 2009 and Bobaljik 2008).

Things are dramatically different with feature transmission under variable binding. The bound variable reading of (58a) is lost if the possessive pronoun is anything but [1SG], (64a). The bound variable reading of (58b) survives with a [3SG] possessive pronoun because its binder, the relative pronoun *who*, is doubly specified for 1st person and 3rd (or no) person, (64b) (see Kratzer 2009 for details). Notice that this reading is lost with a 2nd person pronoun.

- (64) a. Only I did his homework.
 b. I am the only one who takes care of his / your children.

As Kratzer and Heim independently show, variable binding requires ϕ -agreement even in situations where the mismatch in features is semantically warranted; this is quite different

⁴⁷ This seems like an overstatement. Semantic filtering cannot exclude agreement mismatches in semantically opaque features, such as formal gender, formal number, case concord, etc.. The point remains, however, that predication as such is possible in the absence of agreement.

from what we saw with predication. Thus, (65a) is impossible even if uttered by Nina (Kratzer's example) and (65b) is impossible even when each member of the plurality denoted by *they* is a male (Heim's example).⁴⁸

- (65) a. *Nina respects myself. (uttered by Nina)
 b. *They_i each thought he_i had won.
 [cf. They_i each thought they_i had won]

There are two ways to think of the nature of the violations in (65). One way, which I believe is common to Kratzer's and Heim's discussions, is in terms of misvaluation at PF. Pronominal variables start their lives as minimal pronouns; they only acquire their features, at PF, under binding. Since the binders in (65a-b) bear different feature values than the attempted pronominal variables, the latter simply cannot arise in their present forms. A slightly different view would locate the violation already in the syntax. The idea would be that the pronominal forms in (65a-b) must be inherently specified for ϕ -values (since unspecified forms would have ended up matching their binders). This property disqualifies them from entering binding relations, if the following condition is true.

(66) *Condition on bound pronouns*

If *Pron* is a bound variable at LF, then *Pron* is unvalued for any feature that is valued on its binder.

(66) amounts to a well-formedness condition on the syntactic content of bound pronouns. A pronoun which is not minimal would simply fail to be bound. Concretely, suppose that binding recruits a coindexing procedure between a λ -operator and a variable. What (66) stipulates is that only minimal pronouns are visible to this procedure; referential pronouns are not.⁴⁹

At this point the account in terms of PF misvaluation and the account in terms of the condition on bound pronouns look like notational variants. But there is one scenario where they might diverge. Suppose the binder and the pronoun are generated independently with *matching* features. Feature transmission does not apply, since the pronoun is already valued, but misvaluation does not occur either, since the binder and the pronoun bear matching features. On the PF misvaluation view, nothing seems to be violated. On the syntactic well-formedness view, however, variable binding still fails, because the pronoun is not minimal. As we will show in the next section, the interaction of logophoric control with agreement displays a specific grammatical "breakdown" just

⁴⁸ Spathas (2010) and Jacobson (2012) propose an alternative account of (58), in which the apparent semantic inertness of ϕ -features on bound pronouns is limited to their *focus* value. This account does not extend to uninterpreted ϕ -features in contexts involving no focus, such as the bound pronoun/reflexive in (65) or PRO in standard OC; see Landau 2013a for discussion.

⁴⁹ Strictly speaking, the claim is weaker, demanding only features shared by the binder and bindee to be initially unvalued on the latter. Pronouns with inherent features may still function as bound variables as long as these features are absent from their binder. Note that the "bindee" in this formulation may be a constituent of a composite form, accounting for split-bound pronouns (Rullman 2004). Thus, in *Every one of my_i ex-wives_j thinks we_{i+j} were a happy couple*, the bound pronoun is a subpart of *we*, and indeed, this subpart is valued by feature transmission (see Heim 2008 for the explicit derivation).

under these circumstances. The fact that the PF misvaluation account does not afford a natural explanation for this effect while (66) does, then, favors the latter as the correct description of the facts.

3.6 Deriving the OC-NC generalization

The fundamental generalization regulating the distribution of OC complements was stated in (23) and is repeated below.

(67) *The OC-NC Generalization*

[+Agr] blocks logophoric control but not predicative control.

The OC-NC generalization is a *formal* constraint of the grammar; there does not seem to be any deep semantic reason why agreement on the embedded verb should block control in this selective manner. Recall from section 2.1 that predicative control is witnessed in inflected complements (68a), but logophoric control (68b) is blocked once inflection is added (68c) (data from Varlokosta 1993 and Słodowicz 2007).⁵⁰

(68) a. *Predicative control: Greek subjunctive*

O Yanis kseri na kolimbai (*o Giorgos).
the John.NOM knows PRT swim.3SG (*the George.NOM)
'John knows how to swim.'

b. *Logophoric control: Turkish uninflected nominalized complement*

Ahmet_i [PRO_{i/*j} düş-mek]-ten kork-uyor-du.
Ahmet fall.INF-ABL fear-PROG-PST.3SG
'Ahmet was afraid to fall.'

c. *No Control: Turkish inflected nominalized complement*

Ahmet_i [pro_{i/j} düş-me-sin]-den kork-uyor-du.
Ahmet fall.INF-3SG.P-ABL fear-PROG-PST.3SG
'Ahmet was afraid that he would fall.'

The formal nature of the constraint suggests that its proper explanation should be sought in the syntax underlying the two types of control. What is it about the syntax of logophoric control that “clashes” with inflection?

The analysis in the preceding section provides the necessary ingredients of the answer. For each scenario, consider the abstract syntactic relations involved when ϕ -features are present on the embedded T head (irrelevant details omitted; the direction of the arrows tracks the direction of valuation).

⁵⁰ Notice that ‘know’ in (68a) is not used as an attitude verb but has a sense more akin to a dynamic modal.

(69) a. *Predicative control into an inflected complement: Grammatical*

b. *Logophoric control into an inflected complement: Ungrammatical*

The first, bottom-most relation is established between the ϕ -bearing embedded T and PRO. Given that PRO is a minimal pronoun, hence, unvalued, valuation goes from T to PRO (as in (55b)); the valued PRO carries its ϕ -features upon raising to [Spec,Fin]. This much is shared by the two derivations. At this point, however, they diverge. In (69a), independent agreement with the controller DP is possible, similarly to (62), given that predication is not contingent on feature transmission, the conclusion stated above as (60a). In (69b), by contrast, the λ -operator associated with the controller DP cannot establish a binding relation with pro_x in [Spec,CP], since the latter has already been valued by the FinP predicate.⁵¹ Condition (66) then prevents pro_x from becoming a bound variable. The only other option is a free variable, which yields no control, as in (68c). Note that this result would not be guaranteed on the PF misvaluation account of feature mismatch under variable binding; on that view, variable binding would not be hindered by the presence of inherent features on the variable as long as they match those of the binder.

The fundamental distributional law of OC is thus fully derived in a principled manner. It is worth stressing that the semantic and syntactic assumptions that are embodied in the TTC are motivated by evidence quite independent of the OC-NC generalization. The semantics of attitude complements, the properties of predication (more of which to be demonstrated below), the existence of minimal pronouns - all of these receive ample justification outside of control. Moreover, the differential interaction of feature transmission with predication and with variable binding (namely, (60)) is also an independent fact. By letting all these ingredients interact we derive the effects of the OC-NC generalization - adding nothing more. Logophoric control is sensitive to agreement and predicative control is not, because logophoric control implicates variable binding whereas predicative control implicates predication, and variable binding is sensitive to agreement in a way that predication is not.

⁵¹ Although predication does not *have* to transmit features, it *will* do so in case one of its relata is in need of valuation, as the minimal pronoun pro_x is.

At this point we can appreciate the edge that direct variable binding, the option underlying (39c), has over its alternatives (39a-b) – indexical shift and local operator binding. Focusing on the LFs of the three analyses, consider the relation between the binder associated with the controller DP, λx , and the variable associated with PRO.

(70) *Abstract control relations*

- a. Indexical shift (from (40))
 $\lambda x \dots \text{AUTHOR}(i')$
- b. Local operator binding (from (41))
 $\lambda x \dots \lambda z \dots z$
- c. Direct binding of a *de re* variable (from (54))
 $\lambda x \dots x$

Only (70c) provides a genuine explanation for the OC-NC generalization. To the extent that theories in classes (70a) and (70b) posit explicit syntactic correlates of the semantic symbols figuring in the control relation, they may appeal to syntactic Agree as a way of ensuring agreement between $\text{AUTHOR}(i')/\lambda z$ and λx (less naturally in (70a), which would involve a split between the semantic 1st person feature and the morphological person features). But neither approach can prevent $\text{AUTHOR}(i')/\lambda z$ from being ϕ -valued internally to the complement, owing to overt agreement on the embedded T. If the controlled element is a minimal pronoun whose single morphological requirement is to be valued, nothing in the mechanisms of (70a-b) forces this valuation to be performed by λx . On the contrary, bottom-up derivations would value PRO in such cases by the embedded inflection, overgenerating inflected attitude OC complements – in violation of (67). By contrast, this scenario is blocked by the independently justified condition on bound pronouns (66) – only on the assumption that control *is* mediated by direct variable binding, as in (70c).

The point is quite general and worth stressing. The control relation according to (70a) and (the more popular) (70b) is *not registered in the syntax*, hence cannot effect agreement, let alone be vulnerable to agreement outcomes. The control relation according to (70c), on the other hand, *is* registered in the syntax (variable binding must be, given its effect on agreement), hence may well be affected (or blocked) by syntactic agreement.

This is, I believe, a novel and decisive argument in favor of the present proposal, relying on direct binding of a *de re* variable (supplemented by a *de se* presupposition that C^{OC} contributes), and against the two alternatives, over and above the arguments leveled against them in sections 3.4.2-3.4.3.

3.7 Solving the problems with the Agree model

The preceding sections laid out the essential ingredients of the TTC and showed how it accounts for the basic interpretive, syntactic and distributional properties of OC complements. Section 4 will broaden the empirical scope of the theory by looking at the predictions it makes regarding the $[\pm\text{human}]$ value of PRO, implicit control and control

shift. At this point, however, it is useful to take a step back and appreciate the advantages the TTC can claim over its ancestor, the Agree model.

In section 2.3 we listed seven major problems in the model. Briefly, they were the following.

(71) *Problems with the Agree Model*

- a. The stipulative nature of the R-assignment rule (13).
- b. The lack of triggering for the control-inducing Agree operation.
- c. The evidence against semantic tense in infinitives.
- d. The unique ontological status of PRO.
- e. The lack of relation between OC and NOC.
- f. The lack of semantic groundedness.
- g. The nonapplicability to oblique control.

None of these problems persists within the TTC. As to (71a), the former stipulation consisted in the association of [+T,+Agr] with [+R] and other T/Agr combinations with [-R]. This enabled the Agree model to capture the OC-NC generalization. Within the TTC, however, (13) is obsolete and the generalization is derived in a principled way from independently justified properties of predication and variable binding vis-à-vis agreement. Furthermore, there is no direct reference to a [T] feature anymore, its effects being reduced to the presence of a context tuple on the embedded C, which triggers logophoric control.

The triggering problem in (71b) arose because the matrix functional head does not need to enter any Agree relation after having Agreed with the controller, and the [-iR] feature on PRO does not, strictly speaking, call for valuation. These difficulties are removed on the assumption that PRO is a minimal pronoun. By assumption, such entities are not legitimate at the interfaces and therefore must acquire ϕ -values during the derivation. In predicative control, this is accomplished by predication; the formation of the predicate itself is triggered by a [*uD*] feature on Fin. In logophoric control, valuation is accomplished with the help of *pro_x*, a coordinate of the embedded context, which *must* be projected due to the [*uD*] feature on C and *must* be ϕ -valued (as a variable bound by the controller) because it too is a minimal pronoun. Notice that each step in this derivation is mandatory and motivated.

The objection in (71c) to the coherence of "semantic tense" in infinitives does not apply to the TTC, since this criterion is replaced by the independent (and more fundamental) distinction between attitude and nonattitude contexts. PC predicates introduce attitudes (= quantification over contexts) and EC predicates do not. Similarly, the OC-NC generalization makes no reference to [T] but only to attitude complements. There are no rigid temporal correlates of this property and so tense loses its explanatory role in the theory.

(71d) is solved since PRO is no longer unique but rather instantiates a generalized functional element – a minimal pronoun. Such pronouns are used in a variety of contexts

outside control: bound lexical pronouns, bound reflexives, relative pronouns, *pro*-drop and possibly resumptive pronouns and copy-raising pronouns. As to the question why PRO must be phonetically null, I return to it in section 5.

So far we have said nothing of NOC, so problem (71e) of bridging the gap between OC and NOC remains. We return to it in the conclusion, but already can hint to the obvious solution. Since one subtype of OC is now understood as a logophoric phenomenon, and NOC has long been known to be a logophoric phenomenon, the distance between the two is much shorter than it seemed.

Problem (71f) reflected the lack of any explicit semantics in the Agree model and the unmotivated association of Agree itself with variable binding. The problem is even more acute if, as suggested above, feature transmission applies at PF and hence cannot *trigger* semantic variable binding (rather, both are interface responses to syntactic coindexing). The problem is put to rest with the explicit semantics provided in (30) and (54) for predicative and logophoric control, respectively. These meanings are compositionally derived from the associated structures (31) and (53), and are in full harmony with current semantic analyses of control and *de se* attitudes. The operation Agree, in fact, plays no constitutive role in the TTC, and perforce, no semantic consequences need to be attached to it.

The problem of integrating oblique controllers, (71g), was quite serious for the Agree model, for it is a well-established crosslinguistic fact that oblique/PP arguments are not introduced by applicative heads and are inert for agreement relations; hence the assumption that they control via Agree was an oddity. On the assumption that such arguments control via variable binding the problem disappears since oblique and prepositional objects make perfect binders in other contexts of variable binding (e.g., *I talked [with every candidate_i] about his_i prospects*, *We received [from every girl_i] the name of the boy that offended her_i*). Whatever technical device is needed to account for the latter cases (e.g., QR) will automatically cover oblique control as well.⁵²

4. Broadening the empirical basis of the TTC

The TTC is designed to explain *both* the core properties of OC *and* those properties that distinguish its two subtypes - predicative and logophoric control. So far we have focused on the analysis of two distinguishing properties: The (non)obligatory *de se* reading and the (in)compatibility with inflection in the complement. However, a theory of the sort advocated here should make a convincing case that the phenomenology of OC is truly dual in nature and hence calls for a theoretical duality as well. In this section we will see that three other aspects of control - one novel, two often discussed - neatly align with the predicative-logophoric divide, for principled reasons. And in section 5 will briefly touch on two more distinctions sharing this profile, so that the overall empirical picture will be as in the following table.

⁵² Examples like (99) below suggest that oblique arguments can also exercise predicative control. That predication is not limited to bare DP arguments has been shown convincingly by Maling (2001) and Marušič, Marvin and Žaucer (2008).

(72) *Summary of empirical contrasts between the two types of control*

	Predicative Control	Logophoric Control
Inflected complement	✓	*
[–human] PRO	✓	*
Implicit control	*	✓
Control shift	*	✓
Partial control	*	✓
Split control	*	✓

While the phenomena of implicit, shifting and partial control have received a great deal of attention in the descriptive as well as the theoretical literature, the fact that they are *systematically aligned* with the type of control has escaped attention. These correlations cannot be accidental; insofar as they follow from the TTC, they provide strong evidence in its favor.

Section 4.1 addresses the presence or absence of an intrinsic [+human] restriction on PRO in the two types of control; section 4.2 shows and explains why only logophoric control tolerates implicit controllers and section 4.3 does the same for control shift (from subject to object or vice versa).

4.1 [\pm human] PRO

On the minimal pronoun view, PRO is not inherently specified for any semantic feature. If it appears to exhibit any such features, they must arise from the syntactic context. The most obvious source is selection: the nonfinite predicate in the complement clause may require a [+human] subject. Selection may also work indirectly to achieve this result. If the controlling argument is selected to be human (e.g., the subject of *try*, the object of *persuade*), this semantic property will be “transmitted” to PRO since the latter is a variable whose value is provided by the denotation of the controller. These are trivial interactions that do not teach us anything about the underlying mechanisms of control - predication and logophoric anchoring.

Suppose we “turn off” the effects of selection by carefully testing predicates that do not require [+human] arguments (at least on one of their uses). Then we should be able to isolate the pure effect of the *mechanism* of control on the humanness of PRO. Indeed, the two mechanisms make sharply different predictions in this regard. In predicative control PRO is bound by a simple λ -operator; neither the binder nor the bindee carries any inherent semantic feature. In logophoric control, PRO is bound by *pro_x/pro_y*, which is

mapped to the AUTHOR/ADDRESSEE function; since the latter is only defined for humans, the former will too. We thus derive the following prediction.

- (73) a. Predicative control is compatible with [-human] PRO;
- b. Logophoric control is incompatible with [-human] PRO.

Evidence for (73a) was presented in (24), repeated below.

- (74) a. This key_i will serve/do [PRO_i to open the door].
- b. The accident_i is responsible [for PRO_i causing the ship to sink].
- c. The apartment_i failed [PRO_i to meet the federal housing quality standards].
- d. The transmission problem forced the car_i [PRO_i to stop].

Admittedly, PRO must be [+human] under some other verbs of predicative control (e.g., *remember*, *condescend*), but this is an artifact of the selectional requirements of the control predicate, not to be confused with the properties of the predicative relation itself.

Harder to establish is (73b), since verbs of logophoric control nearly always select [+human] arguments, thereby masking the semantic contribution of the minimal pronoun that directly binds PRO. There are very few exceptions, however, and they are quite revealing.

The first example of this sort, (75a), was discovered by Williams (1992). Although Williams explicitly excluded complements from the purview of logophoric control and reserved that term for NOC into (certain) adjuncts and subject clauses, he cogently argued that whenever selection by itself fails to account for the [+human] nature of PRO, logophoric control is evidenced.⁵³ Interrogative complements as in (75a) are, in fact, a species of OC and not NOC, as demonstrated in Landau 2000:39-42; hence they fall under the mechanism of logophoric anchoring proposed in this study. (75a) should be contrasted with (75b), where PRO is licitly controlled by a [+human] controller, and with (75c), where the [-human] matrix subject successfully antecedes a lexical pronoun (not a control relation).

- (75) a. * The note specified where to be filed.
- b. Job specified where to be buried.
- c. The note_i specified where it_i should be filed.

⁵³ The observation that NOC PRO must be [+human] was first made by Chomsky (1981:324-327). It can be illustrated convincingly in examples where pragmatic knowledge favors a conflicting [-human] value, and yet yields to the grammatical condition, e.g. (i)-(iii) from Kawasaki 1993:30. Note that there is no implicit controller in these examples.

- i. [After PRO_{arb} being spoiled in a refrigerator], there is nothing even a good cook can do.
- ii. The government abolished [PRO_{arb} having to be surrounded by fences].
- iii. I read stories about [PRO_{arb} falling off a cliff].

All the declarative verbs, I believe, show this contrast when taking interrogative nonfinite complements (e.g., *indicate*, *declare*, *announce*, *point out*, *reveal*, *say*, *explain*, *make clear*, *remind*, etc.).

Turning to noninterrogative complements, we should note that inanimate controllers can easily stand proxy for humans, especially when the two are related by authorship. Such examples of course do not falsify (73b).

(76) The contract guarantees to provide for all our needs.

These uses can be ruled out by choosing nonfinite predicates that can only apply to the actual inanimate entity and not to the author associated with it. Then the effect of (73b) becomes quite dramatic, see (77a). Once again, the finite complement example (77b) serves to demonstrate that pronominal dependencies as such are not excluded in this configuration.

- (77) a. * The contract guaranteed not to be violated.
 b. The contract_i guaranteed that it_i would not to be violated.

Interestingly, the AUTHOR coordinate in the complement continues to be active even when control shifts to the matrix object (the ADDRESSEE), an observation due to Sag and Pollard (1991). While (78a) is acceptable to some English speakers, (78b) is not, even though a parallel pronominal dependency is fine (78c). This is further evidence for the claim that logophoric control is always mediated by a [+human]-implicated element in the complement clause.⁵⁴

- (78) a. The coach promised Montana_i [PRO_i to be allowed to play in the Super-Bowl].
 b. # The fortune cookie promised Montana_i [PRO_i to be allowed to play in the Super-Bowl].
 c. The fortune cookie promised Montana_i that he_i would play in the Super-Bowl.

Control shift from object to subject provides more opportunities to verify (73b). Verbs like *propose* allow this shift quite easily (79a-b), but control cannot shift to an inanimate subject (79c) (the intended meaning is rendered with a pronoun in (79d)).

- (79) a. Bill / The message proposed to Mary_i [PRO_i to stay calm].
 b. Bill_i proposed to Mary [PRO_i to join her].
 c. * The message_i proposed to Mary [PRO_i to be read aloud].
 d. The message_i proposed to Mary that it_i should be read aloud.

Despite occasional claims to the contrary, even *persuade* and *convince* allow a shift to subject control (when the complement is suitably “de-agentivized”). An empirical study found that sentences like (80) are accepted by 56% of English speakers (32% for

⁵⁴ I return to control shift in section 4.3.

persuade), and their German equivalents are accepted by most German speakers (Panther and Köpcke 1993).

(80) Allan_i convinced Harry [PRO_i to be included generously in his last will].

However, no such shift is possible with an inanimate controller.

- (81) a. The will convinced us_i [PRO_i respect Fred's last wish].
b. * The will_i convinced us [PRO_i to be respected].
c. The will_i convinced us that it_i should be respected.

Overall, then, the data surveyed in this section support both parts of (73), once selectional requirements are factored out.⁵⁵ This striking contrast between the [human] values of PRO in the two classes of OC complements has not been fully recognized before, to my knowledge, let alone explained.⁵⁶

4.2 Implicit control

The idea that OC is a type of a predication relation is of course not new and goes back at least to the early 1980s.⁵⁷ For all its appeal, though, the predication approach to OC faces a number of problems. Most noteworthy of them, as Landau (2010) points out, is that the target of predication must be syntactically present but there is no similar restriction on OC controllers in general.

(82) Condition on syntactic predication

The argument predicated of must be syntactically represented.

(83a-b) show that an implicit object (otherwise possible) cannot saturate an adjectival secondary predicate or a derived, purpose-clause predicate. (83c) shows that the implicit agent of passive is similarly inaccessible to predication.

⁵⁵ It has been proposed that control shift targets a beneficiary argument as the marked controller (Panther and Köpcke 1993, Jackendoff & Culicover 2003). This can account for (78b), (79c) and (81b), but is not sufficient to exclude (75a) and (77a), where control shift is not at stake and yet the same [+human] restriction is attested.

⁵⁶ The point of this section should not be confused with Postal's (2004) observation that PRO displays "antipronominal" distribution in examples like (iii).

- (i) Microsoft went up (= Microsoft's stock's price went up).
(ii) Microsoft_i claimed that its_i stock price would go up.
(iii) *Microsoft_i plans [PRO_i to go up].
(iv) *Microsoft_i claimed that it_i would go up.

Microsoft can be construed as an extended attitude holder, as shown in (ii), so the ungrammaticality of (iii) could be traced to logophoric control (PRO in (iii) is [-human]). This assumption, however, is superfluous in view of (iv), where a pronominal dependency is equally impossible; the latter should be compared with the grammatical examples (75c), (77b), (79d) and (81c). Thus, Postal's antipronominal condition is independent of the logophoricity condition on PRO in attitude contexts.

⁵⁷ See Bach 1979, 1982, Chierchia 1984, 1989, Dowty 1985, Williams 1980, 1987, 1992, 1994, Lebeaux 1984, 1985, Culicover and Wilkins 1986, Clark 1990, Šimík 2012.

- (83) a. John ate *(the meat) raw.
 b. I am now hiring *(people) [for John to work with].
 c. The room was left (*angry at the guests).

In sharp contrast, control by implicit arguments is a pervasive phenomenon (see extensive documentation and discussion in Landau 2013b). In the following examples the parenthesized controller may remain implicit.

- (84) a. George recommended [PRO jogging twice a week] (to Sue).
 b. Bill said (to us) [PRO to be quiet].
 c. It is fun (for Bill) [PRO to watch cartoons].
 d. [PRO planning the event in advance] was quite helpful (to us).

If the relation between, e.g., *Bill* and *to watch cartoons* in (84c) had been a predicative relation, omission of *Bill* should have been impossible. The existence of implicit OC, therefore, is a compelling reason to reject that hypothesis that OC is fully reducible to predication (see Landau 2010).

Nonetheless, a partial reduction may still be motivated. In particular, it may well be the case that a subclass of OC verbs associate with their complements via predication, and precisely for those verbs, the condition in (82) *does* hold. This is indeed the present claim. The cut between the verbs that obey and those that do not obey (82) is the fundamental cut between EC and PC verbs.

- (85) a. The controller with EC verbs must be *explicit*;
 b. The controller with PC verbs may be *implicit*.

While implicit OC is widely recognized, the fact that it is limited to the PC class, to my knowledge, has gone unnoticed. Even more importantly, the very existence of this behavioral split within the class of OC verbs is a puzzle for all existing accounts of OC. But as I shall now demonstrate, it is a true crosslinguistic pattern.

The case of interest is (85a). Its effects can be detected in two contexts: (Attempted) control by the implicit agent of a subject control verb and (attempted) control by the implicit object of an object control verb. Let us consider them in turn.

The very fact that OC by an implicit agent is possible has been called into question. In the literature, the relevant constraint goes by the name “Visser’s Generalization” (VG). It is stated in (86a) and illustrated in (86b).

- (86) a. Visser’s generalization
 Subject control verbs do not passivize.
 b. John was persuaded/*promised to leave.

While *John* is the designated (deep) object controller of *persuade*, the designated controller of *promise* is the implicit agent. The failure of control with the latter was thus taken as evidence for the correctness of VG.⁵⁸

However, VG as stated in (86a) is false. Direct counterevidence comes from impersonal passive variants of subject control constructions (Landau 2000, Kiss 2004, van Urk 2013). English only has a few of them, but even they suffice to refute (86a). Note that the controller in (87) must be taken to be the (suppressed) external argument of *decide/agree/prefer*, hence these are not NOC constructions.

(87) It was decided / agreed / preferred to raise taxes again.

In other Germanic languages, such impersonal passive constructions are much more common, and indeed can be formed with the verb *promise*.

- (88) a. *German* (Růžička 1983)
 ihm war versprochen worden [PRO Hans in die
 him was promised been PRO Hans into the
 Auswahlmannschaft aufzunehmen].
 select-team to.include
 ‘It had been promised to him to include Hans in the select team.’
- b. *Dutch* (van Urk 2013)
 Er werd geweigerd om het verdachte appelsap
 there was refused COMP the suspicious apple.juice
 op te drinken.
 up to drink
 ‘(lit.) There was refused to drink the suspicious apple juice.’

It seems that there is no absolute ban on accessing implicit agents in OC.⁵⁹ van Urk (2011) offers a weaker, more refined version of VG.

- (89) The true VG (revised VG, RVG)
 Implicit subjects cannot control if T agrees with a referential DP.

This formulation correctly distinguishes personal passives, where the matrix T agrees with the deep object (and control fails, (86b) with *promise*) from impersonal passives,

⁵⁸ See Visser 1963, Chomsky 1965:229, 1977, 1980, Jenkins 1972, Anderson 1977, Bach 1979, Williams 1980, Bresnan 1982, Růžička 1983, Koster 1984, Chierchia 1984, Farkas 1988, Larson 1991, Sag and Pollard 1991, Farrell 1993.

⁵⁹ It is also easy to construe an implicit agent as the controller of an adjunct clause.

- i. The ship was sunk to collect the insurance.
- ii. Changes were made before getting proper feedback from the customers.

However, whether these examples truly fall under OC is questionable; see Landau 2013b for discussion.

(90) EC-verbs resist impersonal passives.

The data below confirm this prediction of the predication analysis of EC. Testing the prediction is not trivial, since passive formation in general, and impersonal passives in particular, are subject to specific restrictions which make certain forms unavailable in principle (e.g., some languages require a transitive input, unaccusative and reflexive verbs lack passives, etc.). In all of the examples below, care was taken to test only verbs that occur in the active voice with infinitival complements *and* manifest grammatical passive forms elsewhere in the language; the ungrammatical constructions are thus specifically blocked by (90).

(91) *Hebrew*

- In German, as illustrated in (88a), PC verbs also passivize freely. EC verbs do not.

a. ?? Es wurde aufgehört Zigaretten zu rauchen.
it was stopped cigarettes to smoke
'It was stopped to smoke cigarettes.'

b. ?? Es wurde geschafft / gewagt den Gefangenen zu helfen.
it was managed / dared the prisoners to help
'It was managed/dared to help the prisoners.'

61

(93) *Dutch EC-verbs* (Marcel den Dikken, p.c.)

- *Er werd begonnen (om) sigaretten te roken.
 there was begun (COMP) cigarettes to smoke
 'It was begun to smoke cigarettes.'

Russian also has impersonal passives. Once again, PC verbs give rise to grammatical outcomes and EC verbs do not (judgments by Olga Kagan, p.c.).

(94) a. *Russian PC-verbs*

- Bylo zaplanirovano / obeščano obnovit' zdanie.
 was.NEUT.SG planned.NEUT.SG / promised.NEUT.SG to.renovate building
 'It was planned / promised to rennovate the building.'

b. *Russian EC-verbs*

- *Bylo načato / prodolženo / zakončeno
 was.NEUT.SG begun.NEUT.SG/continued.NEUT.SG/finished.NEUT.SG
 tratit' den'gi na bespoleznye lekarstva.
 to.spend money on useless medicines
 'It was begun / continued / finished / to spend money on useless medicines.'

A striking contrast between the impersonal passive of factive and implicative uses of the verb *forget* (the former a PC-verb, the latter an EC-verb) further confirms (90).

(95) a. Bylo zabyto, što oni zaperli dver'.
 was.NEUT.SG forgotten.NEUT.SG that they locked door
 'It was forgotten that they locked the door.'

b. *Bylo zabyto zaperet' dver'.
 was.NEUT.SG forgotten.NEUT.SG to.lock door
 'It was forgotten to lock the door.'

Let us turn now to the second domain in which the effects of (85a) are observable - object drop with object control verbs. In languages without object *pro* (a syntactically present object), "object drop" amounts to an implicit argument. According to (85), this should be possible with PC verbs but not with EC verbs. Naturally, one should test the prediction in languages in which object drop is relatively productive to begin with, independently of control. English is less than ideal in that respect, but it too manifests implicit object control in a variety of OC contexts, as shown in (84) above. Unfortunately, direct objects are rarely if ever omissible, which makes it impossible to attribute the ungrammaticality of **They forced to leave* specifically to the implicative type of the verb *force* (rather than to a general dislike of direct object drop).

These facts are known under the title "Bach's generalization", which, like Visser's generalization, is false in the general case.⁶⁰ Nonetheless, (85a) suggests that there *is* a

⁶⁰ For a critique of Bach's generalization, see Sag & Pollard 1991, Larson 1991, Williams 1991, Landau 2000, 2013a and Jackendoff and Culicover 2003.

subclass of object control verbs where Bach's generalization holds true; namely, implicative ones (the other EC subclasses, modal and aspectual verbs, do not instantiate object control). To verify this, we need to look outside English.

Ślodołowicz (2008:130-133) observes that in Polish, controller DPs can be freely dropped - except with implicative verbs. A minimal pair is provided by the contribution of aspect: perfective *namówić* 'persuade' is implicative but imperfective *namawiać* is not. Only the latter accepts controller drop, which amounts to implicit control.

(96) a. *Imperfective - desiderative*

Stąd też będę gorąco namawiał ____
 therefore also COP.FUT.1SG warmly persuade.3SG.M
 do spędzenia tego czasu w gronie rodzinnym.
 to spend.NOML.GEN DEM.GEN time.GEN in circle.LOC family.LOC
 'Therefore I will be persuading to spend this time with the family.'

b. *Perfective - implicative*

**pro* namawię ____ do spędzenia tego czasu
 persuade.1PL to spend.NOML.GEN DEM.GEN time.GEN
 w gronie rodzinnym.
 in circle.LOC family.LOC
 'We persuaded to spend this time with the family.'

Ślodołowicz demonstrates that the imperfective *persuade* does not entail that the complement action is accomplished (i.e., it is non-implicative) whereas the perfective *persuade* does (i.e., it is implicative). Thus, the pair in (96) nicely confirms the predictions of (85); the reason behind the ungrammaticality of (96b) is that syntactic predicates (namely, the infinitive) require a syntactic DP to be predicated of.

One reason the so-called Bach's generalization struck many syntacticians as true was the three-way confound between "controller drop", "direct object drop" and "implicative controller drop". If I am correct, only the latter is excluded (universally). It is an accident of English (but not of other languages) that most object controllers are direct objects; further, some of them occur in implicative constructions (e.g., *force DP to VP*) and others in non-implicative constructions (e.g., *ask DP to VP*). Since English direct objects resist omission for independent reasons, the false conclusion was reached that object controllers in general resist omission.

The confound can be resolved in three ways: (i) show that non-implicative indirect/oblique objects may drop (that is, remain implicit); this was illustrated in (84). (ii) show that non-implicative direct objects may drop outside English; this was illustrated in (96a); (iii) show that implicative indirect/oblique objects may not drop. This last scenario will be now illustrated with data from Hebrew.

Hebrew has nine object control verbs that take an oblique controller of the form *al*-DP (*on* DP). They divide to two subclasses as follows.

- (97) a. Implicatives: *kafa* ‘compel’, *hikša* ‘make it difficult’, *hekel* ‘make it easy’, *hišpia* ‘influence’.
 b. Desideratives: *civa* ‘order’, *pakad* ‘command’, *asar* ‘prohibit’, *laxac* ‘pressure’, *hetil* ‘entrust’.

Four out of the five desiderative verbs allow controller drop.⁶¹ This is not surprising, given that indirect/oblique objects are freely omissible in the language and this option extends straightforwardly to control verbs.

- (98) ha-menahel civa / pakad / asar / laxac / (alay)
 the-manager ordered / commanded / prohibited / pressured (on.me)
 lešatef pe'ula ba-misrad.
 to.cooperate in.the-office
 'The manager ordered / commanded / forbade / pressured (me)
 to cooperate in the office.'

In striking contrast, none of the implicative verbs permit controller drop, although the oblique controller is morphologically indistinguishable from the one in (98).

- (99) Gil kafa / hikša / hekel / hišpia *(alay) le'hitpater etmol.
Gil compelled/made.it.difficult/made.it.easy/influenced (on.me) to.quit yesterday
'Gil compelled / made it difficult for / made it easy for / influenced *(me)
to quit yesterday.'

The obligatoriness of the controller in (99), once again, I take to be a direct consequence of the predicative nature of the infinitival complement, which in turn follows from the implicative nature of the matrix verb.

In sum, this section has marshaled evidence in support of (85a). Regardless of its grammatical function - subject, direct object, indirect or oblique object - a DP must be syntactically represented if it controls an predicative complement. Outside predicative constructions, controllers may remain implicit quite freely (up to language-particular constraints, which are crucially independent of control).

4.3 Control shift

Past studies have amply demonstrated that control may shift from subject to object and vice versa under special conditions.⁶² Favorable conditions include: (i) reversal of the

⁶¹ The one that does not is *hetil* ‘entrust’, a restriction which I take to be idiosyncratic. Note that while (85a) does not permit any controller drop with implicative verbs, (85b) does not guarantee that controller drop will be available for all non-implicative verbs in all languages; rather, it states that only non-implicative verbs may ever exhibit it. Independent constraints, mostly lexical and ill-understood, further restrict the range of object drop in any given language.

⁶² See Bresnan 1982, Chierchia 1984, Ružička 1983, Comrie 1984, Farkas 1988, Larson 1991, Sag and Pollard 1991, Panther and Köpcke 1993, Petter 1998, Rooryck 2000, Jackendoff and Culicover 2003, and the summary in Landau 2013b.

authority relations between the two matrix participants; (ii) “de-agentivized” complement clause, and (iii) ideally, *be-allowed-to* complements. Different verbs allow control shift to varying degrees (e.g., *offer/propose* are quite flexible, *urge/recommend* are quite resistant). Furthermore, The precise effect of each of the three conditions listed above is known to vary considerably across speakers and languages.

Typical subject-to-object and object-to-subject control shifts are illustrated in (100) and (101), respectively.

- (100) a. Mary_i was never promised [PRO_i to be allowed to leave].
 b. Grandpa promised the children_i [PRO_i to be able to stay up for the late show].
- (101) a. Jim_i asked Mary [PRO_i to be allowed to get himself a new dog].
 b. Susi_i persuaded the teacher [PRO_i to be allowed to leave early].

Despite the great variability in control shift, certain verbs consistently exclude it, for all speakers. Rooryck (2000), the first to note this fact, called them “verbs of influence”; in fact, they correspond to the only ditransitive verbs that exercise predicative control – the implicative causative verbs (*force, coerce, compel, impose*).⁶³

- (102) ?* She_i forced/compelled her parents [PRO_i to be allowed to quit school].

Note that all the verbs that display control shift, as in (100)-(101), induce logophoric control. On the present view, the contrast is expected. Predication is a bi-unique relation between a DP and a Pred that enter a rigid structural relation: [DP_i [*relator* Pred]] or [Pred [*relator* DP_i]]. No other DP_j may saturate Pred in this structure. Hence the incompatibility of predicative control, an instance of this structure (see in particular (33)), and control shift. Although the testing ground for this prediction is limited (owing to the small number of ditransitive control verbs in the predicative class), it is nevertheless borne out without exception.⁶⁴

In contrast, logophoric control may shift precisely because the *choice* of controller is not grammatically encoded in it. The projected coordinate of the embedded context is not lexically specified; only the need to project *some* coordinate is lexicalized as a selectional [*u*D] feature on the transitive C. The coordinate may be *pro_x*, bound by the matrix author, or *pro_y*, bound by the matrix addressee. The felicity of the result is entirely up to post-LF interpretive processes, which also explains the considerable cross-speaker variability in judgments on control shift (see Uegaki 2011 for an attempt to formalize control shift within the semantics of attitude reports).

⁶³ Rooryck (2007) adds to this class verbs of “actual transfer” (*give, grant, confer*), but these do not easily take control complements.

⁶⁴ Lexicalist accounts that rely on the notion of a benefactive role (see fn. 55) do not seem to offer a viable alternative. Why can the subject of *compel* not be construed as a benefactive, as opposed to the subject of *ask* or *persuade*? One can certainly benefit from compelling others into actions that fit one's needs.

5. Further consequences

The TTC offers new avenues of research on several topics in control theory beyond those already discussed above. In this section I address some of them. Due to space limitations, the discussion will be quite brief and overly simplified, merely aiming to highlight the specific form these traditional issues take in the present context. The issues are: partial control, split control, topic control and controlled lexical pronouns or reflexives.

Partial control. In discussing the Agree model of control (section 2), we mentioned that one of its central concerns was the distinction between exhaustive and partial control. Briefly, EC-predicates force strict coreference between the controller and PRO whereas PC-predicates allow for proper inclusion.

- (103) a. *James condescended to meet thanks to our pressures.
b. James agreed to meet thanks to our pressures.

EC-predicates are precisely those that take nonattitude complements; PC-predicates are those that take attitude complements (see (3)-(4)). Within the current discussion, the distinction is reduced to predicative vs. logophoric control. The task is, then, to explain (i) why is PC blocked in predicative control?; (ii) why is PC allowed in logophoric control?

The answer to question (i) is straightforward. Predicative control cannot be partial because predication cannot be so. As Landau (2007) observed, this unifies the explanations for the failure of partial readings in predicative adjunct control (104a) and secondary predication (104b). We now bring predicative *complement* control, as in (103a), under the same roof.

- (104) a. *John called Mary before meeting in the restaurant.
b. *John called Mary together/while together/as a team/extremely polarized.

The answer to question (ii) is not trivial and requires further investigation. I will mention two possibilities here. Madigan (2008) and Landau (2013a) propose that PC is a type of an associative plural, formed by a null associative morpheme. In the present analysis, this morpheme would map the projected coordinate in [Spec,CP] to a group containing it, possibly reflecting the general capacity of logophoric pronouns to enter a similar inclusion relation with their antecedents (Bianchi 2003). A semantically-oriented alternative is pursued in Pearson 2013, where the notion of *extension* is applied to the embedded context tuple. A context is extended if its individual (=AUTHOR) coordinate is expanded to a set containing the original individual and its temporal coordinate is shifted to the future or the past. In this way, both the referential and the temporal “mismatches” evinced in PC are semantically linked. Naturally, this operation may only apply in logophoric control (and not in predicative control), where a context tuple is present on the embedded C.

Split Control. Split control differs from PC in that PRO is exhaustively and jointly controlled by both matrix arguments. Furthermore, split control licenses syntactic plurality on PRO, unlike PC (see Landau 2000 for discussion).

- (105) a. John_i proposed to Mary_j [PRO_{i+j} to meet each other at 6].
 b. John_i asked Mary_j [whether PRO_{i+j} to get themselves a new car].
 c. John_i discussed with Mary_j [which club PRO_{i+j} to become members of].

In fact, most ditransitive control verbs allow split control under certain circumstances. A small class, however, excludes it, and it is the same one that excludes control shift: ditransitive implicative verbs.

- (106) * Bill_i forced/compelled George_j [PRO_{i+j} to deal with themselves first].

Given that these control verbs induce predicative control, this fact is expected, as predication in general disallows split readings.

- (107) John_i met Mary_j angry_{i/j/*i+j} (*at each other).

The question why and how split control is licensed in logophoric complements is pretty much open. A concrete proposal by Madigan (2008a, 2008a) holds that a designated exhortative mood marker (lexicalized as *ca* in Korean) induces a [SUM] feature of PRO, which takes the AUTHOR and ADDRESSEE variables and returns their plural sum. This proposal can be naturally integrated with the current analysis. As long as we assume that the sum operator applies to coordinates of the embedded context, we can understand why split control is restricted to complements that introduce such contexts, namely, attitude complements. The details, of course, remain to be worked out, as well as a closer investigation of how split control depends on the lexical semantics of the matrix verb.

Topic control. Recall that the subjecthood of PRO, in the present system, is a by-product of locality principles rather than a substantive condition on the controlled element itself (as in, e.g., the LFG or GB treatments of control). This leads one to expect that nonsubject positions will be controllable insofar as these locality principles are respected. Interestingly, a case in point might be Tagalog, which has often been described as alternating between “semantic” control (of the Actor role) or syntactic control (of the subject position); see Kroeger 1993 and Falk 2006. The former type is exemplified in (108a) and the latter in (108b). According to Kroeger (1993), control verbs that select Action complements (like *plan*) exercise Actor-control: The downstairs Actor is the controllee, regardless of its grammatical function. In (108a), it is a genitive object, the subject being the goal (*mother*). By contrast, verbs of orientation (like *insist*) exercise subject-control: The downstairs subject is the controllee, regardless of its semantic role. In (108b) it is the nominative theme of the embedded verb (OV – objective voice; AV – active voice; DV – dative voice).

- (108) a. Binalak niya-ng [bigyan PRO_{GEN} ng-pera ang-Nanay].
 PERF.plan.OV 3SG.GEN-COMP DV.give GEN-money NOM-mother
 ‘He planned to give mother (some/the) money.’
- b. Nagpilit si-Maria-ng [bigy-an PRO_{NOM} ng-pera ni-Ben].
 PERF.AV.insist.on NOM-Maria-COMP give-DV GEN-money GEN-Ben
 ‘Mary insisted on being given money by Ben.’

There is, however, an alternative interpretation of the facts.⁶⁵ While Kroeger takes the traditional view that the voice system in Tagalog tracks grammatical functions, an alternative, increasingly popular view takes it to reflect discourse functions. In particular, the voice markers can be analyzed as verbal affixes registering which argument of the verb has been singled out as the clausal topic (the *ang*-NP; see Carrier-Duncan 1985, Richards 2000 and Pearson 2005). On this analysis, (108b) instantiates standard control of the embedded subject, but (108a) appears to involve *topic control*, a *prima facie* oddity.

We can make sense of topic control, on the current theory, as a situation where PRO-movement targets a Topic Phrase projection rather than FinP. This predicative TopP may then combine directly with the matrix verb, yielding predicative topic control, or serve as the complement of C under attitude verbs, yielding logophoric topic control. Since nonsubjects may freely be topicalized, this will give rise to control of nonsubject topics, as in (108a).

Naturally, one would like to know what makes Tagalog (and possibly other Philippine languages) special in allowing topic control; this challenge is no greater than explaining, on the traditional view of the voice system, what makes it special in allowing Actor control.⁶⁶ The important point is that the current theory affords a simple account of this unusual pattern of control, which calls for no ad-hoc assumptions.

Controlled lexical pronouns/reflexives. Recent work indicates that phonological nullness is not a defining feature of the controlled subject in OC, as classical work assumed. The most well-studied exceptions come from Korean (Yang 1985, Madigan 2008b, Lee 2009) and Hungarian (Szabolcsi 2009), where the controllee is a lexical reflexive or a pronoun (see also Sundaresan 2010 on Tamil). Interestingly, in both cases the use of an overt controllee is associated with focus.

⁶⁵ See Landau 2013b:111-115 for further discussion.

⁶⁶ Here is one possibility. Topicalization, like other discourse-related phenomena, must be phonologically expressed in language. For this reason, null arguments normally cannot be topicalized. Tagalog, however, is remarkable in that the topic is not only obligatory but also consistently indexed on the verb (in the form of a "voice" marker). This makes null or minimal pronouns eligible for topicalization (hence, TopP a suitable complement to C^{OC}), the phonological requirement being satisfied by the voice morphology.

- (109) a. Inho_i-ka Jwuhi_j-eykey [PRO_{j/*i} / **caki_{j/*i}-ka** cip-ey ka-la-ko] *Korean*
 Inho-NOM Jwuhi-DAT self-NOM home-LOC go-IMP-C
 mal-ha-yess-la.
 tell-do-PST-DC
 ‘Inho told Jwuhi to go home.’ (i.e., that *only* Jwuhi should go home)
- b. Nem felejtettem el [én is aláírní a levelet]. *Hungarian*
 not forgot-1SG PFX I too to-sign the letter.ACC
 ‘I didn’t forget to bring it about that I too sign the letter.’

Although the question is not directly addressed in these studies, it seems that this option is equally available in complements of logophoric and predicative control; note that the directive *tell* belongs to the former type and the implicative *forget* to the latter. This implies that the lexicalized element is PRO rather than the projected coordinate *pro*, since only PRO is present in both constructions. Because PRO, on the present analysis, is nothing but a minimal pronoun that creates an operator-variable chain by movement, the obvious question is under what conditions such chains result in spellout at PF.

Although space limitations do not permit a detailed study of the PF-algorithm that negotiates syntactic chains (see Landau 2006b), one can identify some common patterns. In contrast to minimal pronouns bound by lexical DPs/QPs, those bound by minimal operators (like PRO) are often unpronounced. Relevant cases include the operator-trace chains in *tough*-movement, parasitic gap constructions, nonfinite relative clauses and purpose clauses. The notable exception is relative pronouns in finite complements, which are pronounced optionally or obligatorily, depending on context. A closer look reveals that pronunciation is normally forced by external factors, unrelated to the minimal pronoun per se.

- (110) a. This is the man (who) I met.
 b. This is the man (who) Mary thought met me.
 c. This is the man who/that/* \emptyset met me.
 d. This is the man to *(whom) I listened.

Structurally case-marked relative pronouns (accusative or nominative) are optionally silent, (110a-b). If forced to be pronounced, like the nominative *who* in (110c), it is due to independent reasons (in this case, probably, parsing-related), which are satisfied equivalently by *who* or *that*. Oblique and inherently case-marked relative pronouns are necessarily pronounced (110d), again reflecting an independent condition on the recoverability of inherent case (Pesetsky 1998).

In this context, we may think of the [+Focus] feature that sanctions the lexicalization of the minimal pronoun PRO in (109) in analogy to the [+wh] feature that sanctions the lexicalization of the minimal pronoun *who* in (110a-b).⁶⁷ In both cases, pronunciation is

⁶⁷ Many languages never lexicalize the relative operator, suggesting that the spelled out trigger in the English construction is [+wh] rather than [+Rel]. Furthermore, nonfinite environments somehow suppress even the optional spellout of structurally case-marked relative pronouns (e.g., *The man (*whom) to invite is*

optional, indicating that these features are somewhat less rigidly mapped to PF than, e.g., [Case:Dat] or [Case:Gen].⁶⁸ Naturally, many questions remain open about the deeper rationale behind these distinctions, as well as their different expression in various languages. Still, such questions about the syntax-PF interface have a familiar flavor and are fruitfully explored in current work, a promising sign for the present approach.

6. Conclusion

The central thesis of this study is that OC into complement clauses divides into two subtypes, predicative and logophoric control. Analytically, they differ as follows.

(111) Analytic contrasts between the two types of control

	Predicative Control	Logophoric Control
Semantic type of complement	non-attitude: <d,<e,<s,t>>>	attitude: <<e,<κ,e>>,<κ,t>>
Head of complement	transitive Fin _[uD]	transitive C _[uD]
Control and Agreement are established via:	predication	predication+ variable binding

More specifically, all OC complements (disregarding restructuring) host a minimal pronoun subject (PRO), which turns the complement into a derived predicate upon movement to the FinP projection. In predicative control, this derived predicate applies directly to the controlling argument. In logophoric control, it applies to another minimal pronoun, projected by C, itself bound by the controlling argument. This “mediated route” is only available in attitude complements, whose head encodes the belief/desire contexts of evaluation from the perspective of the attitude holder. The minimal pronoun projected by this head is associated with a special *de re* presupposition which amounts to *de se* - the interpretive hallmark of logophoric control.

Theoretically, the only residue from the previous Agree model is the distinction between a “direct” and an “indirect” (C-mediated) control route. Importantly, Agree as such plays no role in establishing the semantic antecedence relation, its function restricted to

John); this may be another factor militating against the lexicalization of PRO, at least in standard nonfinite complements.

⁶⁸ Sundaesan (2010) develops a cyclic-spellout account of the nullness of PRO, which is keyed to the “defectiveness” of the embedding C. The function of [+Focus], on that account, is to render C nondefective.

transmitting ϕ -values to the PRO-predicate at PF. Empirically, the TTC derives the major result of the Agree model, restated as the OC-NC generalization, providing a genuine explanation for the universal absence of inflected attitude OC complements. As discussed in detail, no other alternative analysis of the semantics of OC can come to terms with these agreement facts.

In addition, the TTC explains why the effects of [\pm human] PRO, implicit and shifting control selectively attach to predicative or logophoric control in the way they do. Notably, the explanation rests on standard properties of predication and variable binding and calls for no ad hoc adjustments.

In the final remarks I would like to point out that the TTC offers a particularly appealing unification of complement OC with other types of control. As is well known, nonfinite clauses in subject position display NOC, and the same is generally true of adjuncts in initial position;⁶⁹ right-edge adjuncts can be marginally forced into NOC readings if set off by an intonational break. Although the relation between the controller and PRO in NOC need not be as local as in OC, a rich descriptive literature has shown that it displays the very same interpretive restriction that we have identified in one type of OC: logophoricity.⁷⁰ That NOC PRO must be [+human] was already noted in fn. 53, cf. the oddity of (112a-b). Notice that even a human controller must either be the author or addressee of the proposition in which the controlled clause is embedded, cf. the contrast in (112c-d).

- (112) a. [After PRO_{arb} being spoiled in a refrigerator], there is nothing even a good cook can do.
 b. The government abolished [PRO_{arb} having to be surrounded by fences].
 c. We indicated to Mary_i that [PRO_i exposing herself] really embarrassed John.
 d. * The rumors about Mary_i had it that [PRO_i exposing herself] really embarrassed John.

As Williams (1992) pointed out, however, right-edge adjuncts are free of such restrictions, and do not even require a human controller. Landau (2013b) cites the following examples.

- (113) a. This book_i was out of print [before PRO_i becoming a bestseller last summer].
 b. The crops_i are harvested [only PRO_i to rot in the barns].
 c. Around here, it_i always snows before [PRO_i raining].

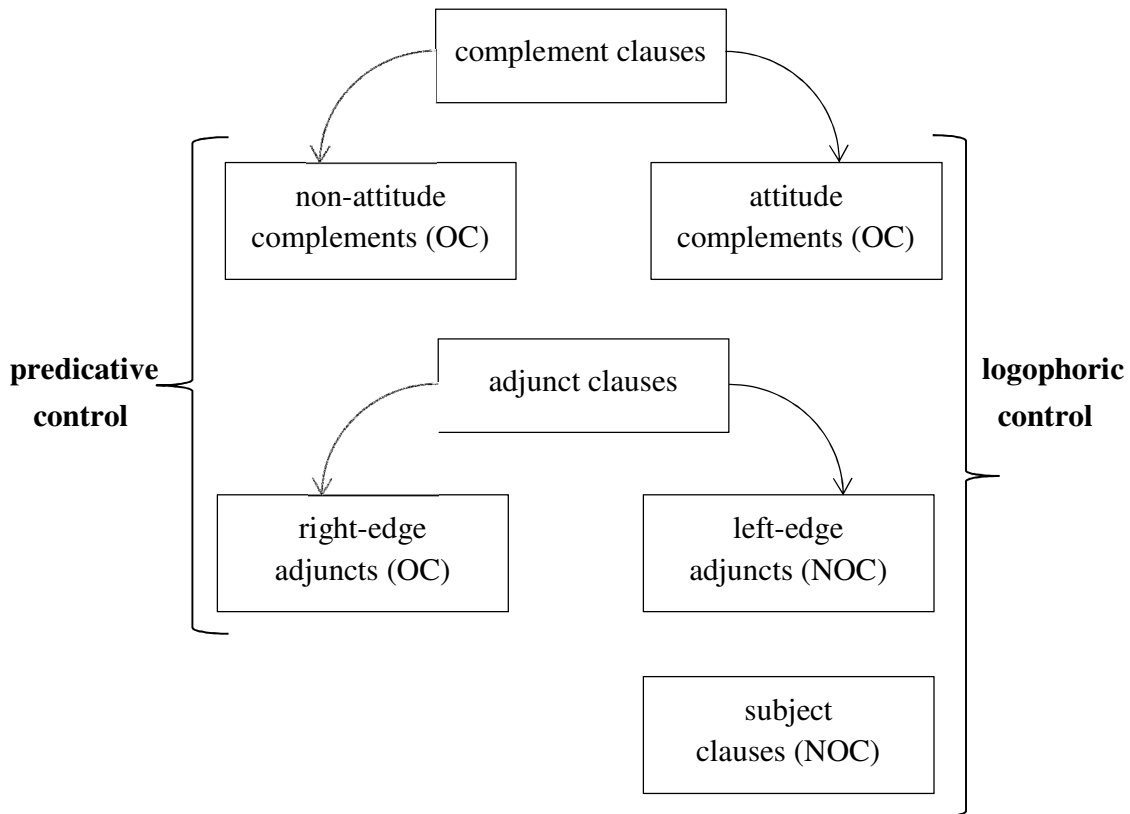

Let us assume that Williams' insight was correct: Adjuncts exhibit two types of control, predicative or logophoric, depending on the configuration. Consequently, just as complements contrast in whether they impose a [+human] value on PRO (see section

⁶⁹ This is a simplified picture since not all adjuncts are alike, and certain kinds may display OC clause-initially (see Mohanan 1983, Landau 2013a:226). Trivially, nonclausal adjuncts (bare adjectives or participles) do not project the functional structure needed to mediate NOC.

⁷⁰ See Kuno 1975, Williams 1992, Kawasaki 1993, Lyngfelt 1999, Manzini and Roussou 2000, Rooryck 2000, Landau 2000, 2001, 2007, 2013a.

4.1), so do adjuncts. What emerges from these observations is that the constructional *heterogeneity* of control conceals an analytic *duality* that cuts across traditional divides.

(114) *The duality of control at large*

On this unifying view, NOC and (logophoric) OC are not distinguished at all at the fundamental level of mechanism, contra to popular belief. Rather, the difference boils down to the fact that the projected coordinate of the logophoric C (in our notation, pro_x or pro_y) is a bound variable in OC but a free variable in NOC. This may reflect a deeper, simple difference: The coordinate variable in OC necessarily picks (via the concept-generator in [Spec,CP]) the attitude context specified on the embedded C, but may pick *any* attitude context (including the utterance context) in NOC. Ultimately, the contrast seems to be grounded in the fact that complements are selected whereas subjects and adjuncts are not.⁷¹

While much more can and should be said about the analysis of NOC, these remarks hopefully suggest some fruitful directions for future research on this and related topics. If they hold some kernel of truth, then the TTC may form the basis of a truly comprehensive theory of control.

⁷¹ A related observation is that a predicate may restrict the range of complementizers that head its complement but cannot do so with complementizers of subject/adjunct clauses (Bennis 2000).
