

Nested Interrogatives and the Locus of *wh*

OMER PREMINGER[†]

Massachusetts Institute of Technology

Abstract

This paper discusses the behavior of certain *wh*-island-violating (but felicitous) constructions in Hebrew. These constructions exhibit two important characteristics: superiority effects, and a sensitivity to the distinction between short vs. long *wh*-movement.

I propose an analysis based on the assumption that in Hebrew, the relevant *wh*-feature resides on a head lower than C^0 , but CP is still equipped with a single specifier position that can be utilized for the purpose of successive-cyclic *wh*-movement. The proposal is shown to account for the behavior of these constructions with respect to the aforementioned characteristics, and is supported by the existence of independent cases of \bar{A} -movement to a position below the overt complementizer in Hebrew.

1. Introduction

In this paper, I discuss the properties of a particular construction in Hebrew, in which several interrogative clauses are nested within one another. This gives rise to multiple *wh*-movement—but unlike familiar cases (e.g., Bulgarian; [Rudin 1988](#)), no single clausal periphery ends up overtly hosting more than one *wh*-element.

The construction in question is shown to exhibit two interesting characteristics. The first is a robust superiority pattern, with respect to the base-generated positions of the moved *wh*-elements. The second is, quite surprisingly, the existence of *wh*-island effects. Though the very existence of these constructions might suggest that the *wh*-Island Condition ([Ross 1967](#))—or any more contemporary successor to it—is inoperative in Hebrew, this is shown not to be the case. Rather, a more intricate distinction, involving short *wh*-movement vs. long *wh*-movement, is shown to regulate the distribution of *wh*-island effects.

I then present an analysis of these phenomena, based on the assumption that in Hebrew, the relevant *wh*-feature is located in a projection lower than CP. This assumption is independently motivated by the existence of another type of \bar{A} -movement in Hebrew that targets a position below the overt complementizer. Crucially, even though the overt landing site of *wh*-movement is below C^0 , CP itself still provides a single specifier position through which successive-cyclic *wh*-movement may occur.

This analysis is shown to predict both the superiority and the *wh*-islandhood phenomena exhibited by this construction.

2. Prologue: Multiple *wh*-Movement in Hebrew

Hebrew performs its *wh*-movement overtly. If one takes care to exclude *Echo-Question* readings, interrogatives with only one *wh*-element become ungrammatical unless the *wh*-element has moved:

[†]Thanks to Irena Botwinik, Danny Fox, Ivona Kucerova, Idan Landau, Shigeru Miyagawa, David Pesetsky, Ivy Sichel, an anonymous reviewer, and audiences at *Edges in Syntax* (especially Luigi Rizzi), the 22nd *Conference of the Israeli Association for Theoretical Linguistics (IATL 22)*, and *MIT Ling-Lunch*. Also, thanks to Tal Siloni and Julia Horvath, who got me hooked on this phenomenon in the first place.

All errors are my own.

- (1) a. [et mi]₁ Dan pagaš t₁?
 ACC who Dan met
 ‘Who did Dan meet?’
 b. * Dan pagaš et mi?
 Dan met ACC who

In addition, there is a seemingly independent limitation prohibiting the appearance of more than one wh-element at a given clausal periphery, as shown in (2a–b). This is not a ban on two wh-elements being base-generated in the same clause; *Pair-List* questions such as (3a), in which one of the internal arguments of *natan* ‘gave’ undergoes wh-movement and the other remains in situ, are felicitous. Nor is this a ban on movement of more than one wh-element base-generated in a given clause. As shown in (3b), two internal arguments of *natan* ‘gave’ can both undergo wh-movement, provided they do not land at the same clausal periphery.¹

- (2) a. * [ma]₁ [le-mi]₂ Dan natan t₁ t₂?
 what DAT-who Dan gave
 b. * [le-mi]₁ [ma]₂ Dan natan t₂ t₁?
 DAT-who what Dan gave
 (3) a. [ma]₁ Dan natan t₁ le-mi?
 what Dan gave DAT-who
 ‘What did Dan give to whom?’
 b. [ma]₂ Dina šaxexa [le-mi]₁ Dan natan t₁ t₂?
 what Dina forgot DAT-who Dan gave
 ‘[What]₂ did Dina forget [to whom]₁ Dan gave t₂ t₁?’

Indeed, (3a) and (3b) represent the two types of multiple-wh questions one finds in Hebrew. The first type, which also exists in English, is *Pair-List* questions—or more accurately, *Tuple-List* questions (where a *pair* is just a specific instantiation of a *tuple*, with a size of $n = 2$). Like their English counterparts, the answer to these is a list—or under certain circumstances, a singleton—of pairs/tuples, with each element in a given pair/tuple corresponding to one wh-element in the original question. The sentence in (3a) above is one such case, and further examples are given below:²

- (4) a. [mi]₁ t₁ axal ma?
 who ate what
 ‘Who ate what?’
 b. [mi]₁ t₁ amar [_{CP} še-mi ne’elam]?
 who said that-who disappeared
 ‘Who said that who disappeared?’
 c. [mi]₁ t₁ amar [_{CP} še-Dan tilfen le-mi]?
 who said that-Dan phoned DAT-who
 ‘Who said that Dan phoned whom?’

¹ As will be shown in section §3, this is by no means a sufficient condition for the grammaticality of a Hebrew question involving multiple wh-elements.

² As the felicity of (5a–d) indicates, Hebrew does not manifest an English-like *That-Trace Effect*.

- d. [mi]₁ t₁ šalax ma le-mi?
 who sent what DAT-who
 ‘Who sent what to whom?’
- (5) a. [mi]₁ Yosi xašav [CP še-(t₁-)axal ma]?
 who Yosi thought that-ate what
 ‘Who did Yosi think ate what?’
- b. [mi]₁ Yosi xašav [CP še-(t₁-)amar [CP še-mi ne’elam]]?
 who Yosi thought that-said that-who disappeared
 ‘Who did Yosi think said that who disappeared?’
- c. [mi]₁ Yosi xašav [CP še-(t₁-)amar [CP še-Dan tilfen le-mi]]?
 who Yosi thought that-said that-Dan phoned DAT-who
 ‘Who did Yosi think said that Dan phoned whom?’
- d. [mi]₁ Yosi xašav [CP še-(t₁-)šalax ma le-mi]?
 who Yosi thought that-sent what DAT-who
 ‘Who did Yosi think sent what to whom?’

The second type of multiple-wh questions, shown in (3b) above, is what I will call *Nested Interrogatives*. These sentences involve multiple interrogative clauses nested within one another, with one wh-element moving to the periphery of each of the interrogative clauses. Consider the following example:

- (6) Yosi yada [CP [et ma]₂ Dan šaxax [CP [le-mi]₁ Rina natna t₁ t₂]].
 Yosi knew ACC what Dan forgot DAT-who Rina gave
 ‘Yosi knew [what]₂ Dan forgot [to whom]₁ Rina gave t₂ t₁.’

The meaning of Nested Interrogatives is decidedly different from that of Pair/Tuple-List questions. In (6), what Yosi knows is something about individuals, not about pairs. A rough schematization of the meaning of (6) is given below:

- (7) Yosi knew the extension of $\{x \mid \text{Dan forgot what the extension of } \{y \mid \text{Rina gave } x \text{ to } y\} \text{ was}\}$

If the structure that is embedded in (6) appears as a matrix question, the conversationally appropriate answer would be one about *individuals*, not about *pairs*:

- (8) A: [et ma]₂ Dan šaxax [CP [le-mi]₁ Rina natna t₁ t₂]?
 ACC what Dan forgot DAT-who Rina gave
 ‘[What]₂ did Dan forget [from whom]₁ Rina gave t₂ t₁?’
- B: [et ha-sefer ha-xadaš] / #[et ha-sefer ha-xadaš, le-Roni]
 ACC the-book the-new ACC the-book the-new DAT-Roni
 ‘The new book / #The new book, to Roni.’

In this paper, I will be primarily concerned with Nested Interrogatives in Hebrew, the phenomena they manifest, and the analysis of these phenomena.

3. Nested Interrogative Phenomena

3.1. Superiority Effects

The first phenomenon exhibited by Nested Interrogatives in Hebrew that I will discuss is a robust superiority pattern.³ Consider the following contrast:

- (9) a. [et ma]₂ Dan šaxax [CP [mi]₁ t₁ axal t₂]?
 ACC what Dan forgot who ate
 ‘[What]₂ did Dan forget [who]₁ t₁ ate t₂?’
 b. * [mi]₁ Dan šaxax [CP [et ma]₂ t₁ axal t₂]?
 who Dan forgot ACC what ate

Notice that (9a) is not simply a case of *mi* ‘who’ remaining in situ. First, as noted in section §2, wh-elements in Hebrew can only remain in situ in *Echo-Question* and *Pair/Tuple-List* readings, and (9a) is not such a case. Second, the same superiority effects can be replicated in cases that do not involve wh-subjects at all:

- (10) a. [et ma]₂ Dan šaxax [CP [le-mi]₁ siparti t₁ [CP še-Rina axla t₂]]?
 ACC what Dan forgot DAT-who told.1SG that-Rina ate
 ‘[What]₂ did Dan forget [to whom]₁ I told t₁ that Rina ate t₂?’
 b. * [le-mi]₁ Dan šaxax [CP [et ma]₂ siparti t₁ [CP še-Rina axla t₂]]?
 DAT-who Dan forgot ACC what told.1SG that-Rina ate

Further examples are given below:

- (11) a. [mi]₂ Dan šaxax [CP [le-mi]₁ siparti t₁ [CP še-(t₂-)niceax ba-taxarut]]?
 who Dan forgot DAT-who told.1SG that-won in.the-contest
 ‘[Who]₂ did Dan forget [to whom]₁ I told t₁ [t₂ won the contest]?’
 b. * [le-mi]₁ Dan šaxax [CP [mi]₂ siparti t₁ [CP še-(t₂-)niceax ba-taxarut]]?
 DAT-who Dan forgot who told.1SG that-won in.the-contest
 (12) a. [et ma]₂ Dan šaxax [CP [mi]₁ t₁ xašav [CP še-Roni axal t₂]]?
 ACC what Dan forgot who thought that-Roni ate
 ‘[What]₂ did Dan forget [who]₁ t₁ thought that Roni ate t₂?’

³In many respects, the data discussed here goes back to Reinhart’s (1981) paper, which is itself a response to Rizzi (1978). Indeed, the analysis proposed in section §5 is in many ways inspired by Reinhart’s analysis, though the latter was formulated in a decidedly different framework (namely, early *Government and Binding* theory). The reader may therefore find it surprising that this paper uses very few data points from Reinhart’s (1981) paper. The reasons for this are twofold:

First, Reinhart’s paper conflated three types of \bar{A} -movement in Hebrew: interrogative wh-movement, topicalization, and relativization with an overt pronoun. Topicalization in Hebrew has distinctly different properties than interrogative wh-movement does (e.g., a much reduced sensitivity to islands). The (optional) overt pronoun found in Hebrew relativization structures is arguably very different from the overt wh-pronoun found in English relative clauses, and is perhaps no more than a topicalized resumptive pronoun (as its morphological form would suggest). Therefore, the data used in this paper—unless otherwise stated—is carefully restricted to interrogative wh-movement.

Second, the current analysis places a great deal of importance on the distinction between long and short wh-movement, and the examples are carefully chosen to control for this distinction. While these differences were noticed by Reinhart, they were considered “dialectal”, and very few minimal pairs were constructed around this property of the derivation.

- b. * [mi]₁ Dan šaxax [CP [et ma]₂ t₁ xašav [CP še-Roni axal t₂]]?
 who Dan forgot ACC what thought that-Roni ate

The emergent pattern—already observed by Reinhart (1981)—is that for the most part, Nested Interrogatives in Hebrew seem to observe a “non-intersection” constraint. Informally, multiple wh-movements must be nested, rather than crossing.⁴ Similar patterns have been observed for other languages that allow Nested Interrogatives (e.g., French, Italian, and some varieties of English), and were originally handled by positing a general principle of the language faculty against crossing dependencies (see Fodor 1978, Kayne 1984, Pesetsky 1982, among others).

In section §5, I will show that at least for Hebrew, there is no need to postulate any such principle. Rather, the emergent pattern follows naturally from independently motivated conditions on the economy of movement.

There is an interesting observation to be made here regarding the interaction of syntactic superiority and semantic interpretation. Typical superiority effects, of the kind found in *Pair/Tuple-List* questions, do not affect interpretation; in those cases, there is a single putative meaning (a “target LF”, so to speak), as in (13), and superiority simply determines which syntactic structure will be used to express this meaning:

- (13) {⟨x, y⟩ | Dan thinks that x ate y}
 (14) a. [Who]₁ does Dan think [CP t₁ ate what]?
 b. * [What]₁ (does) Dan think [CP who ate t₁]?
 (15) a. [mi]₁ Dan xošev [CP še-(t₁-)axal ma]?
 who Dan thinks that-ate what
 ‘[Who]₁ does Dan think t₁ ate what?’
 b. * [ma]₁ Dan xošev [CP še-mi axal t₁]?
 what Dan thinks that-who ate

In other words, the putative meaning of (14b) is the same as the meaning of (14a)—namely, (13); superiority effects simply determine that the meaning in (13) will be expressed in English as (14a), rather than (14b). The same holds for (15a) vs. (15b) in Hebrew.

⁴In fact, it seems likely that Nested Interrogatives in Hebrew obey this constraint invariably, and that apparent deviations from this pattern, which were noted by Reinhart (1981), can be attributed to the freedom of merging order among internal arguments of Hebrew ditransitives—a fact that was not yet discussed at the time. Since then, it has been occasionally noted in the literature that the internal arguments of ditransitive verbs in Hebrew behave as though they were equidistant to the clausal periphery. Consider the following paradigm, involving multiple-wh questions in a *Pair-List* configuration:

- (i) a. [et ma]₁ Dan xašav še-hexzarta t₁ [le-mi]?
 ACC what Dan thought that-returned.2SG DAT-who
 ‘What did Dan think that you returned to whom?’
 b. [le-mi]₁ Dan xašav še-hexzarta t₁ [et ma]?
 DAT-whom Dan thought that-returned.2SG ACC what
 ‘To whom did Dan think that you returned what?’
 (from Preminger 2005:(183a-b), p. 73)

The grammaticality of both (ia) and (ib) is significant, since Hebrew normally exhibits the same kind of superiority effects in *Pair-List* questions as English does (e.g., when subjects vs. internal arguments are involved).

Similar observations appear in Landau (1994), among others.

Superiority effects in Nested Interrogatives are quite different, in this respect. The meaning that the ungrammatical (9b) would have if it were grammatical is different from the meaning of the grammatical (9a):

- (16) a. *meaning*(9a) =
 $\{x \mid \text{Dan forgot what the extension of } \{y \mid y \text{ ate } x\} \text{ was}\}$
 b. *putative-meaning*(9b) =
 $\{y \mid \text{Dan forgot what the extension of } \{x \mid y \text{ ate } x\} \text{ was}\}$

The relation between (10a) and (10b) is similar:

- (17) a. *meaning*(10a) =
 $\{x \mid \text{Dan forgot what the extension of } \{y \mid \text{I told } y \text{ that Rina ate } x\} \text{ was}\}$
 b. *putative-meaning*(10b) =
 $\{y \mid \text{Dan forgot what the extension of } \{x \mid \text{I told } y \text{ that Rina ate } x\} \text{ was}\}$

Thus, syntactic superiority actually limits the set of meanings that can be expressed using the Nested Interrogative construction in Hebrew—the meanings in (16b) and (17b) simply cannot be expressed using this construction. In itself, this is not a particularly shocking observation; there are languages (e.g., prescriptive English) that bar this construction completely, so some paraphrase must obviously be available. Nevertheless, this effect is still noteworthy, in that it restricts the set of possible interpretations for which the Nested Interrogative construction could be employed.

3.2. The Distribution of *wh*-Islandhood

As the very existence of Nested Interrogatives demonstrates, the conventional *wh*-Island Condition (Ross 1967) does not hold of Hebrew. This does not mean, however, that no *wh*-island effects exist. Compare the felicitous (18a–c) to the infelicitous (19a–c):

- (18) a. [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Dan šalax t₁ t₂]?
 which book forgot.2SG DAT-who Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Dan sent t₂ t₁?’
 b. ?[et ma]₂ Rina xašva [CP še-Dan ša’al [CP [le-mi]₁ Roni šalax t₁ t₂]]?
 ACC what Rina thought that-Dan asked DAT-who Roni sent
 ‘[What]₂ does Rina think that Dan asked [to whom]₁ Roni sent t₂ t₁?’
 c. ?[et ma]₂ yadata [CP še-Rina zaxra [CP [mi-mi]₁ Dan lakax t₁ t₂]]?
 ACC what knew.2SG that-Rina recalled from-who Dan took
 ‘[What]₂ did you know that Rina recalled [from whom]₁ Dan took t₂ t₁?’
 (19) a. * [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Rina xašva [CP še-Dan šalax t₁ t₂]]?
 which book forgot.2SG DAT-who Rina thought that-Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Rina thinks that Dan sent t₂ t₁?’
 b. * [et ma]₂ Rina ša’ala [CP [le-mi]₁ Dan xošev [CP še-Roni šalax t₁ t₂]]?
 ACC what Rina asked DAT-who Dan thinks that-Roni sent
 ‘[What]₂ did Rina ask [to whom]₁ Dan thinks that Roni sent t₂ t₁?’

- c. * [et ma]₂ yadata [CP [mi-mi]₁ Rina zaxra [CP še-Dan lakax t₁ t₂]]?
 ACC what knew.2SG from-who Rina recalled that-Dan took
 ‘[What]₂ did you know [from whom]₁ Rina recalled that Dan took t₂ t₁?’

Notice that in terms of the relative nesting of filler-gap dependencies, (19a–c) mirror the relations in (18a–c). Similarly, (19a–c) represent the same superiority configurations as their felicitous counterparts in (18a–c). Therefore, neither of these properties (the nesting of filler-gap dependencies, or superiority effects) can explain the contrast in grammaticality between the two sets.

The difference that underlies the attested contrast seems to be one of *short wh-movement* (movement of a constituent to the periphery of the clause where it was base-generated) vs. *long wh-movement* (movement of a constituent to the periphery of a clause outside of the one where it was base-generated).

In all of the infelicitous cases (19a–c), there is at least one clausal periphery through which more than one wh-element has passed, such that each of the relevant wh-elements has undergone long wh-movement. In the felicitous cases (18a–c), for every given clausal periphery, at most one wh-element has moved long-distance through that periphery.

Another, perhaps simpler way to describe these facts is as follows: short wh-movement does not “clog” the left periphery of the clause in Hebrew, while long wh-movement does. This means that once a wh-element has moved out of a given clause, the sole escape hatch of that clause is no longer available for movement of other wh-elements.

4. Background: \bar{A} -Movement Below C⁰ in Hebrew

Hebrew has an extremely productive (and pragmatically, not very marked) operation of topicalization, which targets a position below the overt complementizer. This phenomenon, which I will refer to as *Sub-Complementizer Topicalization* (henceforth, *SCT*), is exemplified below:⁵

- (20) Dan amar [CP še-[et ha-sefer limud]₁ hu kvar kara t₁].
 Dan said that-ACC the-book teaching he already read
 ‘Dan said that he had already read THE TEXTBOOK.’

To establish that SCT is indeed an instance of \bar{A} -movement, let us consider some relevant diagnostics. First, SCT behaves as \bar{A} -movement with respect to the licensing of *P(arasitic)G(ap)s*—namely, it is able to license them:

- (21) Dan amar [CP še-[et ha-sefer ha-ze]₁ hu kara t₁ (mi-)bli liknot e].
 Dan said that-ACC the-book the-this he read from-without buy.INF PG
 ‘Dan said that he had read THIS BOOK_i without buying it_i.’

Compare this with a clear-cut case of A-movement, of the kind involving the raising predicate *amur* (‘supposed to’; *lit.* ‘said.PASV’), which predictably fails to license PGs:

⁵The use of the term “topicalization” here is somewhat misleading. Topicalization and focalization in Hebrew result in the same word orders, exhibit the same syntactic properties, and are mutually exclusive in the same clause—suggesting that the syntactic mechanism referred to here as *SCT* may underlie either of the two discourse functions.

- (22) a. Dan amar [_{CP} še-[ha-sefer ha-ze]_i amur t_i le'orer maxloket].
 Dan said that-the-book the-this supposed wake.INF controversy
 'Dan said that this book is supposed to cause controversy.'
- b. * Dan amar [_{CP} še-[ha-sefer ha-ze]_i amur t_i le'orer maxloket (mi-)bli
 Dan said that-the-book the-this supposed wake.INF controversy from-without
 liknot e].
 buy.INF PG

In addition, the landing site of SCT fails to act as an A-binder. Note, for example, the lack of Condition C effects in (23b), below, with respect to the pronoun *acma* ('herself') and the R-expression *Rina*:⁶

- (23) a. Dan amar [_{CP} še-Rina_i ohevet et acma_i].
 Dan said that-Rina likes ACC herself
 'Dan said that Rina_i likes herself_i.'
- b. Dan amar [_{CP} še-[et acma_i]_i Rina_i ohevet t_i].
 Dan said that-ACC herself Rina likes
 'Dan said that Rina_i likes HERSELF_i.'

Compare this with a prototypical case of A-movement—namely (24b), which is the verbal passive counterpart of (24a):

- (24) a. ? Dan amar [_{CP} še-ha-mištara acra ota_i [axrey še-Rina_i xazra]].
 Dan said that-the-police arrested ACC.her after that-Rina returned
 'Dan said that the police arrested her_i after Rina_i came back.'
- b. * Dan amar [_{CP} še-[hi_i]_i ne'ecra t_i [axrey še-Rina_i xazra]].
 Dan said that-she arrested.PASV after that-Rina returned

Once again, SCT fails to pattern with A-movement, patterning instead with \bar{A} -movement.

Borer (1995) claims that SCT in Hebrew is in fact a case of scrambling, manifesting a combination of the properties of A-movement and the properties of \bar{A} -movement. The central piece of evidence for non- \bar{A} behavior is the lack of *W(eak)C(ross)O(ver)* effects in SCT constructions, as shown below:

- (25) a. Dan yode'a [_{CP} še-kol yeled_i ohev et ima šelo_i].
 Dan knows that-every boy loves ACC mother his
 'Dan knows that every boy_i loves his_i mother.'
- b. Dan yode'a [_{CP} še-[et ima šelo_i]_i kol yeled_i ohev t_i].
 Dan knows that-ACC mother his every boy loves
 'Dan knows that every boy_i loves HIS_i MOTHER.'

⁶Note that accusative-marked noun-phrases—such as *et acma* ('ACC herself') in (23b)—do give rise to Condition C violations under normal circumstances:

(i) šixnati ot-a_i/*_j še-Rina_j tenaceax.
 convinced.1SG ACC-3SG.FEM that-Rina win.FUT
 'I convinced her_i/*_j that Rina_j will win.'

However, as argued by Lasnik and Stowell (1991), WCO effects are far from being a perfect diagnostic for \bar{A} -movement. Specifically, they do not arise when non-quantificational variable binding is involved; appositive relativization is such a case—and as shown in (26b), WCO effects fail to appear in appositive relative clauses in Hebrew as well:

- (26) a. John will speak to this girl_i, who her_i mother truly loves *e*.
 b. Dina tedaber im ha-yeled ha-ze_i, še-im-o_i be-'emet ohevet *e*.
 Dina speak.FUT with the-boy the-this that-mother-his in-truth loves
 'Dina will speak to this boy_i, who his_i mother truly loves.'

It seems quite plausible that if appositive relative clauses are *non-quantificational* by nature (as opposed to *wh*-questions, for example)—and this obviates the potential WCO violation in (26a–b)—then SCT is non-quantificational in precisely the same way. Broadly speaking, the information-structural import of SCT bears similarity to that of an appositive relative clause: removing an appositive relative clause has no effect on the truth-conditions of a sentence, and undoing SCT in a sentence where it has applied seems to have no truth-conditional effects, either.

In light of the existence of such confounding factors, the lack of WCO effects in SCT can hardly be taken as straightforward evidence for a lack of \bar{A} -properties. Moreover, Borer (1995) fails to note the failure of the landing site of SCT to \bar{A} -bind (as shown in (23b), above). The latter bolsters the idea that WCO effects fail to appear not because the landing site of SCT displays \bar{A} -position properties, but rather due to some other property of the construction (such as the specific non-quantificational nature of the operator-variable relations created by SCT, as suggested above).

5. An Analysis of Hebrew Nested Interrogatives

In this section, I present the proposed analysis of Nested Interrogatives in Hebrew, and demonstrate how it derives the phenomena discussed in section §3.

5.1. The Proposal

5.1.1. Projections

In light of the SCT facts discussed in section §4, it is reasonable to assume that Hebrew has an \bar{A} -operator position below its overt complementizer. In §3.2, it was demonstrated that *short wh-movement* (movement of a *wh*-element to the periphery of the clause where it was base-generated) does not “clog” the left periphery—i.e., subsequent movement of another *wh*-element out of the same clause is possible.

Taken together, these facts suggest that much like SCT, *wh*-movement in Hebrew targets a position below the complementizer. Thus, the properties embodied by the CP layer in English are not shared by a single projection in Hebrew—but rather distributed between at least two projections:

- (27) a. HIGHER PROJECTION:
 i. serves as the clausal escape-hatch
 ii. hosts the overt complementizer (presumably, as its head)

wh-movement), and disallowed in English, Dutch, and German (which do not have a clause-internal landing-site for wh-movement).

Interestingly, Hebrew also allows RD:

- (29) Dan hizmin mišehu la-mesiba, nidme li še-et Dina.
 Dan invited someone DAT.the-party seems DAT.1SG that-ACC Dina
 ‘Dan invited someone to the party, and I think it was Dina.’ (*lit.* ‘..., and I think that Dina.’)

The felicity of (29) is predictable if Hebrew wh-movement—like its Hungarian counterpart—targets a position inside the clause (such as the position targeted by SCT).

I will therefore adopt the following naming conventions, with respect to the projections outlined in (27a–b):

- (30) a. HIGHER PROJECTION: CP
 i. serves as the clausal escape-hatch
 ii. hosts the overt complementizer (presumably, as its head)
 b. LOWER PROJECTION: FocP
 i. is the complement of the head of the higher projection (in (27a/30a))
 ii. is the locus for \bar{A} -operator interpretation

It may be that in Hebrew, FocP is none other than TP (the position taken by Borer 1995), in which case (30b) is a notational equivocation—but I do not think the case has been made for such a unification (see section §4). I leave this open for further research.

5.2. Empirical Coverage

Let us examine how the proposal in §5.1 fares in accounting for the phenomena exhibited by Nested Interrogatives, as presented in section §3.

At this point, it is worthwhile to make explicit some fundamental (and hopefully uncontroversial) assumptions. First, allowing C^0 to have multiple specifiers would obviate any wh-island effects, because there would always be an additional vacant edge position to be utilized at the CP phase. As shown in §3.2, Hebrew does manifest at least some wh-island effects—therefore, Hebrew C^0 cannot be allowed to have multiple specifiers.

Second, wh-island effects are often attributed to the *P(hase)I(mpenetrability)C(ondition)* (Chomsky 2000, 2001), the modern successor to *Subjacency* (Chomsky 1986) and/or the explicit *wh-Island Condition* (Ross 1967). I will remain neutral here as to whether the PIC is actually a grammatical primitive, or rather derivable from other principles of the grammar.⁷ In what follows, I will merely assume that the PIC is a valid generalization.

5.2.1. A Featurally Explicit Account of Successive Cyclic wh-Movement

Given the proposal in §5.1, Foc⁰ in Hebrew interrogative clauses is equipped with a [*wh*] feature, which attracts a wh-element. For concreteness, let us assume a clause with exactly two wh-elements, *wh*₁ and *wh*₂; and for the purposes of this sub-section alone, let us disregard their relative hierarchy. Foc⁰ will attract one of these wh-elements:

⁷See Richards (2007b) for a particularly intriguing proposal, deriving not only the PIC, but also the identity of the phase heads and their properties, from considerations having to do with the selection of lexical sub-arrays.

What will be the fate of wh_2 ? Since there are no remaining active $[wh]$ features in the current clause, the situation faced by wh_2 is comparable to the situation faced by a wh -element located inside an English declarative clause. Consider the embedded clause in (32), below:

(32) Who do you think (that) Dan met?

This exceedingly simple example represents a long-standing problem with respect to the *Probe-Goal* theory of movement. We know that *who* makes it out of the embedded clause in (32). Locality (e.g., the PIC) tells us that this cannot happen in one fell swoop; rather, it happens successive-cyclically, through the intermediate $[Spec, CP]$. However, none of this explains what drives this movement: why does *who* vacate its position within the embedded clause in the first place?

Claiming that *who* moves to the edge of the embedded CP in (32) so it can later check a feature on the matrix C^0 amounts to computational look-ahead. Positing a syntactically active feature on the embedded C^0 runs into an immediate problem—explaining how this feature does not crash the derivation in simple declaratives, where there is no wh -element that passes through C^0 :

(33) I think (that) Dan met Dina.

Claiming that wh -feature-equipped declarative C^0 is selected for the numeration in precisely those environments where it is needed (e.g., in (32) but not in (33)) simply relegates the aforementioned look-ahead property from the derivation to the numeration, but the problem remains.

Several more interesting approaches have been taken to this problem. While it is beyond the scope of this paper to seriously evaluate and compare these proposals (see Preminger 2007, 2008 for some discussion), I will mention two of them here. First, one may seek to refine the two-way division of syntactic features. In Chomsky's (1995) system, features come in one of two flavors: they can be syntactically active, in which case they are unvalued, and will crash the derivation if they arrive at the interfaces unchecked; alternatively, they can be syntactically inactive, in which case they are valued, and are amenable to interpretation at the interfaces. Pesetsky and Torrego (2007) argue that the bi-conditional implicated in this description should be severed. In particular, they argue for the existence of syntactically active features that are not uninterpretable. With respect to the case at hand, suppose that elements that undergo \bar{A} -movement—in Hebrew, this would encompass wh -elements, foci, and topics—all bear an uninterpretable but valued operator-feature, whose value depends on the nature of the moving element: $[uOp_{wh}]$, $[uOp_{foc}]$, or $[uOp_{top}]$, respectively. Suppose further that declarative C^0 bears an interpretable but unvalued operator-feature: $[iOp_\phi]$. This $[iOp_\phi]$ feature will attract a wh -element—if present, as in (32)—to $[Spec, CP]$, though it will not render $[uOp_{wh}]$ interpretable, due to the absence of a value on the probe.⁸ Crucially, however, $[iOp_\phi]$ will not crash the derivation of a clause without a wh -element, as in (33).

Alternatively (and these alternatives are not, in principle, mutually exclusive), one may argue that the existence of probe-driven movement does not rule out the possibility of foot-driven movement—in other words, movement driven by the needs of the moved element, rather than its landing site (or some element close to its landing site). It has been argued that the existence of such movement is an empirical necessity (see [van Craenenbroeck 2006](#), [Platzack 1996](#), [Preminger 2007, 2008](#), [van Riemsdijk 1997](#); see also [Lasnik’s 1995 *Enlightened Self-Interest*](#)). In this case, one could say that *who* moves out of the embedded clause in (32) because it needs to be in an operator position, and one is unavailable within the embedded clause.

For expository purposes, I will adopt the former approach (based on interpretable-but-unvalued operator-features on C^0)—though nothing that follows hinges on this particular implementation, nor rules out alternative approaches to this specific issue.

The derivation of (32) would thus proceed by means of $[iOp_\phi]$ on C^0 attracting *who*. Being an unvalued feature, $[iOp_\phi]$ will fail to turn $[uOp_{wh}]$ on *who* into an interpretable feature (see fn. 8); the latter will therefore remain visible to a higher probe (e.g., one that is located at the matrix periphery). This is also the reason why a wh-element (such as *who*) cannot be left in the $[Spec,CP]$ position of a declarative clause:

(34) * I think who_1 (that) Dan met t_1 .

The uninterpretable $[uOp_{wh}]$ on the wh-element must eventually be rendered interpretable (e.g., by $[iOp_{wh}]$ on the matrix C^0 , as in (32)).

In the case of a declarative clause that does not contain a wh-element, $[iOp_\phi]$ on C^0 will reach the $C(onceptual)I(ntentional)$ interface (or “LF”) unchanged. This is a harmless result: being interpretable, $[iOp_\phi]$ will not cause the derivation to crash; it will simply be semantically vacuous.

Of course, long-distance wh-movement out of declarative clauses, as in the English (32), exists in Hebrew as well:

(35) et-mi ata xošev še-Dan pagaš?
 ACC-who you think that-Dan met
 ‘Who do you think that Dan met?’

The likely conclusion is that declarative C^0 in Hebrew (as in the embedded clause in (35)) is just like its English counterpart—namely, equipped with $[iOp_\phi]$. However, in Hebrew, the same phenomenon exemplified by (32/35) is also found with wh-movement out of embedded interrogative clauses. As an example, recall (18a), repeated below:

⁸In this, I depart from the assumptions made by [Pesetsky and Torrego \(2007\)](#), as their system does not address the look-ahead problem discussed in the text. This departure from [Pesetsky and Torrego’s \(2007\)](#) proposal can be characterized as follows:

- (i) an interpretable feature $[iF]$ on a probe P will render $[uF]$ on the goal interpretable only if $[iF]$ on P is valued

Note that this caveat is irrelevant to the kind of *Probe-Goal* relations proposed by [Chomsky \(1995\)](#)—since in those cases, it is the probe that bears the *uninterpretable* instance of the feature, while the goal bears the interpretable instance (e.g., in the relation between the ϕ -probe on T^0 and a subject DP, *number* on T^0 is uninterpretable, while *number* on a subject DP is interpretable).

- (18) a. [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Dan šalax t₁ t₂]?
 which book forgot.2SG DAT-who Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Dan sent t₂ t₁?’

A straightforward account for this would be to assume that in Hebrew, interrogative C^0 —just like declarative C^0 —is equipped with $[iOp_\phi]$.⁹ As a result, the derivation will proceed as follows. First, $[iOp_{wh}]$ on Foc^0 will attract the hierarchically closest wh-element to $[Spec, FocP]$ (as shown in (31), repeated below):

When C^0 is merged, its $[iOp_\phi]$ feature will attract the other wh-element to $[Spec, CP]$, giving rise to the following pattern:

Given that CP is a phase, only wh_2 will be accessible to further computation. In particular, the $[iOp_{wh}]$ feature on a higher Foc^0 will be able to attract wh_2 , as shown below:

⁹In fact, nothing goes wrong if one assumes that both declarative C^0 and interrogative C^0 , both in Hebrew and in English, are equipped with $[iOp_\phi]$. Since interrogative C^0 in English is also equipped with $[iOp_{wh}]$, the latter will render the $[uOp_{wh}]$ feature found on wh-elements interpretable (i.e., changing it to $[iOp_{wh}]$)—and these wh-elements will therefore move no further. The “superfluous” unvalued $[iOp_\phi]$ on interrogative C^0 in English will be prevented from attracting another wh-element by the restriction of CP to a single specifier position (and just like in the case of declaratives that lack a wh-element, it will result in harmless semantic vacuity when $[iOp_\phi]$ reaches the semantic interface). The relevant difference between Hebrew and English would then be restricted to the availability, in Hebrew, of a valued operator-feature (i.e., $[iOp_{wh}]$) on a projection lower than CP.

This version is arguably more uniform, and therefore perhaps more appealing, than the one presented in the text—but this is significant only if one commits oneself to an approach based on interpretable-but-unvalued features, with respect to driving long-distance wh-movement.

Thus, successive-cyclic wh-movement out of Hebrew interrogative clauses (and in fact, out of any Hebrew clause) is on a par with wh-movement out of English declarative clauses.

Moreover, such an account also derives another generalization about wh-movement in Hebrew. Recall that in section §2, it was pointed out that there is a seemingly independent constraint against the appearance of more than one wh-element at a given clausal periphery—as demonstrated in (2a–b), repeated below:

- (2) a. * [ma]₁ [le-mi]₂ Dan natan t₁ t₂?
 what DAT-who Dan gave
 b. * [le-mi]₁ [ma]₂ Dan natan t₂ t₁?
 DAT-who what Dan gave

As was shown in (3a–b) (also repeated here), this is not a constraint against two wh-elements being base-generated in the same clause (as in (3a)), or even against two wh-elements that were base-generated in the same clause both undergoing wh-movement (as in (3b)):

- (3) a. [ma]₁ Dan natan t₁ le-mi?
 what Dan gave DAT-who
 ‘What did Dan give to whom?’
 b. [ma]₂ Dina šaxexa [le-mi]₁ Dan natan t₁ t₂?
 what Dina forgot DAT-who Dan gave
 ‘[What]₂ did Dina forget [to whom]₁ Dan gave t₂ t₁?’

The current approach captures this generalization: while the [*uOp_{wh}*] feature on the first wh-element is rendered interpretable (i.e., changed to [*iOp_{wh}*]) by the corresponding [*iOp_{wh}*] feature on Foc⁰, the [*iOp_φ*] feature on C⁰ does not have the same effect on the second wh-element (see the discussion above). Therefore, a wh-element that has been attracted to C⁰ by [*iOp_φ*] must eventually be attracted by a higher Foc⁰, to have its own [*uOp_{wh}*] feature rendered interpretable (i.e., changed to [*iOp_{wh}*]).

This is completely equivalent to the behavior of English declarative C^0 —as exemplified in (34), repeated below—and is fully expected if the featural content of Hebrew interrogative C^0 is on par with English declarative C^0 (as proposed earlier).

(34) * I think wh_1 (that) Dan met t_1 .

The ungrammaticality of (2) is therefore of the same nature as the ungrammaticality of (34).¹⁰

To recapitulate, while two wh -elements can derivationally occupy the same clausal periphery in Hebrew, only one—the one in [Spec,FocP]—can have its [uOp_{wh}] operator-feature rendered interpretable (i.e., changed to [iOp_{wh}]) at a given clausal periphery; the other will invariably have to move on, to a higher [Spec,FocP], in order to have its own [uOp_{wh}] feature rendered interpretable (i.e., changed to [iOp_{wh}]). As a result, no two wh -elements will ever appear overtly at the same clausal periphery in Hebrew.

Crucially, no novel mechanisms are invoked here that are not independently needed to account for wh -movement out of embedded declaratives in English.

5.2.2. The Superiority Pattern Derived

As shown in §3.1, when there are multiple interrogative clausal peripheries in a given sentence, the lower periphery attracts the higher wh -element, in essence obeying *Shortest Attract*. The higher clausal periphery then attracts the remaining (lower) wh -element. As discussed in §3.1, this pattern is in line with a large body of work regarding the requirement that \bar{A} filler-gap dependencies be nested, rather than crossing (see Fodor 1978, Kayne 1984, Pesetsky 1982, among others).

However, given the current proposal, there is no need for recourse to anything other than general, independently motivated primitives governing the economy of syntactic movement—and in particular, the structural proximity between probe and goal.

Let us assume that something like *Shortest Attract*, the *Minimal Link Condition*, or any other comparable economy condition on movement, is operative. Upon merger of Foc^0 , its [iOp_{wh}] feature will attract the hierarchically closest wh -element in its search domain. For expository purposes, suppose that wh_1 asymmetrically c-commands wh_2 . In this state of affairs, it will necessarily be wh_1 that is attracted to [Spec,FocP]:

Assuming an unvalued [iOp_ϕ] feature on C^0 (as outlined in §5.2.1), wh_2 will then be attracted to [Spec,CP]. Note that even though wh_1 is closer—in fact, both the copy of wh_1 in [Spec,FocP]

¹⁰Note that superiority effects could rule out at most one of the two sentences in (2a–b), and in fact probably rule out neither (see fn. 4).

and the topmost A-position of wh_1 are closer—its wh -feature has been rendered interpretable and checked by $[iOp_{wh}]$ on Foc^0 , hence it is invisible for the current computation. We therefore arrive at the following state of affairs:¹¹

As discussed in §5.2.1, the fact that CP is a phase means that only wh_2 will be available for subsequent computation, and in particular, movement into a higher clause.¹² By hypothesis, such movement into a higher clause will be the result of a higher Foc^0 attracting wh_2 from the embedded [Spec,CP], as schematized below:

¹¹On the effects (or lack thereof) of an additional phase at the VP level (e.g., v^*P), see §6.1.

¹²In fact, for this particular configuration, one need not appeal to the phasehood of CP at all. Assuming a hierarchically higher-up probe P , wh_2 will be the closest syntactically active wh -element in P 's domain. However, as will become evident during the discussion of islandhood phenomena in Nested Interrogatives (in §5.2.3), the phasehood of CP is indeed operative.

Given the general schema in (40), let us turn to analyzing the examples presented in §3.1. As a first example, recall (9a–b), repeated below:

- (9) a. [et ma]₂ Dan šaxax [CP [mi]₁ t₁ axal t₂]?
 ACC what Dan forgot who ate
 ‘[What]₂ did Dan forget [who]₁ t₁ ate t₂?’
 b. * [mi]₁ Dan šaxax [CP [et ma]₂ t₁ axal t₂]?
 who Dan forgot ACC what ate

Consider the embedded clause in (9a–b), abstracting away from certain irrelevant details:

- (41) [TP mi [axal [et ma]]]
 who ate ACC what

In (41), both wh-elements are at their A-positions. The element *mi* (‘who’) is hierarchically higher (i.e., equivalent to *wh*₁ in the general schema, in (40)). When Foc⁰ probes for wh-elements, it will attract *mi* (‘who’), moving it to [Spec,FocP] and rendering it syntactically inactive:

- (42) 
 (42) [FocP [mi]₁ [TP t₁ [axal [et ma]]]]
 who ate ACC what

Now, when C⁰ probes, only *et ma* (‘ACC what’) remains as an active wh-elements, and it will be moved to [Spec,CP]:

- (43) 
 (43) [CP [et ma]₂ [FocP [mi]₁ [TP t₁ [axal t₂]]]]
 ACC what who ate

Being at [Spec,CP], *et ma* (‘ACC what’) is at the edge of the phase, and therefore accessible for further computation. Thus, it subsequently moves to the matrix [Spec,FocP], as illustrated below:

- (44) 
 (44) [FocP [et ma]₂ Dan šaxax [CP t₂ [FocP [mi]₁ [TP t₁ [axal t₂]]]]]
 ACC what Dan forgot who ate

This successfully derives the grammatical (9a).

In the ungrammatical (9b), the matrix Foc⁰ putatively attracts *mi* (‘who’). Since both the A-position of *mi* (‘who’), and its position at the left periphery of the embedded clause, are within the complement domain of the embedded C⁰, neither is accessible to probing by the time the matrix Foc⁰ probes (by virtue of the PIC). This renders (9b) an illicit computation.

As a further example, recall (10a–b), repeated below:

- (10) a. [et ma]₂ Dan šaxax [CP [le-mi]₁ siparti t₁ [CP še-Rina axla t₂]]?
 ACC what Dan forgot DAT-who told.1SG that-Rina ate
 ‘[What]₂ did Dan forget [to whom]₁ I told t₁ that Rina ate t₂?’
 b. * [le-mi]₁ Dan šaxax [CP [et ma]₂ siparti t₁ [CP še-Rina axla t₂]]?
 DAT-who Dan forgot ACC what told.1SG that-Rina ate

The most-embedded clause in (10) is declarative, as evinced by the overt declarative complementizer *še* ('that'). As a result, there is no feature on the most-embedded Foc^0 to attract *et ma* ('ACC what'), and it cannot move there.

Since *et ma* ('ACC what') is attracted by the most-embedded C^0 rather than the most-embedded Foc^0 , it moves to the most-embedded $[\text{Spec}, \text{CP}]$, and is accessible for movement to the higher clause:

- (45) $[\text{TP siparti le-mi} \quad [\text{CP} [\text{et ma}]_2 [\text{C}' \text{še-Rina axla } t_2]]]$
told.1SG DAT-who ACC what that-Rina ate

When Foc^0 immediately above the TP in (45) probes, it will attract the hierarchically-higher *le-mi* ('DAT-who'), moving it to $[\text{Spec}, \text{FocP}]$:

- (46) $[\text{FocP} [\text{le-mi}]_1 [\text{TP siparti } t_1 [\text{CP} [\text{et ma}]_2 \text{še-Rina axla } t_2]]]$
DAT-who told.1SG ACC what that-Rina ate

The C^0 immediately above the FocP in (46) will attract the remaining wh-element, namely *et ma* ('ACC what'):

- (47) $[\text{CP} [\text{et ma}]_2 [\text{FocP} [\text{le-mi}]_1 [\text{TP siparti } t_1 [\text{CP } t_2 \text{še-Rina axla } t_2]]]]]$
ACC what DAT-who told.1SG that-Rina ate

Being at the edge of the intermediate CP, *et ma* ('ACC what') will then be the only candidate for successive wh-movement to the periphery of the matrix clause:

- (48) $[\text{FocP} [\text{et ma}]_2 \text{Dan šaxax} [\text{CP } t_2 [\text{FocP} [\text{le-mi}]_1 [\text{TP siparti } t_1 [\text{CP } t_2 \text{še-...}]]]]]]]$
ACC what Dan forgot DAT-who told.1SG that-...

This successfully derives the grammatical (10a).

In the ungrammatical (10b), the matrix Foc^0 attempts to attract *le-mi* ('DAT-who'), all copies of which are within the complement domain of the embedded C^0 , and thus inaccessible by that point in the derivation (by virtue of the PIC).

5.2.3. The Distribution of wh-Islandhood Derived

As noted in §3.2, short wh-movement (i.e., movement of an element to the periphery of the clause where it was base-generated) does not “clog” the left periphery of the Hebrew clause. Long wh-movement, however, does exactly that: it renders the clause from which the wh-element was extracted an island.

If Foc^0 carries a $[\text{iOp}_{\text{wh}}]$ feature—as proposed in §5.1—it provides a left-peripheral landing site for a wh-element (i.e., $[\text{Spec}, \text{FocP}]$), which crucially does not involve the CP projection. Thus, when an element moves to the periphery of the clause where it was base-generated, it need not pass through $[\text{Spec}, \text{CP}]$ at all. This was schematized in (37), repeated below:

The availability of a left-peripheral landing-site, distinct from the clausal escape hatch, explains why short wh-movement will not give rise to islandhood.

Long wh-movement, however, necessarily involves a wh-element moving out of the CP in which it was base-generated. Since the FocP projection is within the complement domain of C^0 , it is not accessible to computation outside of the CP phase. Therefore, movement to [Spec,FocP] (as described above) would not suffice to facilitate the wh-element escaping that phase. The element must exit the complement domain of C^0 entirely—and in Hebrew, that means passing through the single specifier position of CP:

This renders the single edge position of CP occupied, preventing any further extraction from within the CP phase—which explains why long wh-movement does give rise to islandhood in Hebrew.

Let us now turn to analyzing the examples presented in §3.2. Recall (18a), repeated below:

- (18) a. [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Dan šalax t₁ t₂]?
 which book forgot.2SG DAT-who Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Dan sent t₂ t₁?’

The embedded clause in (18a) starts out as follows:

- (50) [TP Dan šalax [le-mi] [eyze sefer]]
 Dan sent DAT-who which book

By hypothesis, the embedded Foc⁰ carries a [iOp_{wh}] feature. Consequently, it probes for a wh-element and attracts *le-mi* (‘DAT-who’):¹³

- (51) [FocP [le-mi]₁ [TP Dan šalax t₁ [eyze sefer]]]
 DAT-who Dan sent which book

Crucially, this state of affairs leaves [Spec,CP] available for subsequent movement of a wh-element out of the same embedded clause. Hence, when C⁰ (or more accurately, [iOp_φ] on C⁰) probes, it will attract *eyze sefer* (‘which book’):

- (52) [CP [eyze sefer]₂ [FocP [le-mi]₁ [TP Dan šalax t₁ t₂]]]
 which book DAT-who Dan sent

The phrase *eyze sefer* (‘which book’) is now at the edge of the CP phase, rendering it accessible to further computation. It will then be attracted by [iOp_{wh}] on the matrix Foc⁰, moving it to its surface position in the matrix periphery:

- (53) [FocP [eyze sefer]₂ šaxaxta [CP t₂ [FocP [le-mi]₁ [TP Dan šalax t₁ t₂]]]]
 which book forgot.2SG DAT-who Dan sent

Now recall (19a), repeated below—the ungrammatical counterpart of (18a), above:

- (19) a. * [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Rina xašva [CP še-Dan šalax t₁ t₂]]?
 which book forgot.2SG DAT-who Rina thought that-Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Rina thinks that Dan sent t₂ t₁?’

As discussed in §3.2, the difference that underlies the contrast between (18a) and (19a) is one of short vs. long wh-movement. Specifically, the crucial factor is whether there exists a clausal periphery through which two wh-elements have passed, such that both wh-elements have undergone long-distance wh-movement.

To see how this follows from the current proposal, recall the restriction of the Hebrew CP to a single specifier. This entails that at most one element can ever “completely escape” a given clause—i.e., move to a position strictly outside of the clause. In (19a), however, both wh-elements

¹³It just so happens that superiority, as discussed in §5.2.2, is immaterial to this step in the derivation, since two internal arguments are involved. See fn. 4.

(*eyze sefer* ‘which book’, and *le-mi* ‘DAT-who’) appear overtly outside of the most embedded clause, where both were base-generated. Given the PIC, this means that each must have passed through the specifier of the most embedded CP—but this is impossible, since by hypothesis, there is only one [Spec,CP] position.

The derivation of (19a) therefore incurs a PIC violation, with respect to either the link of *eyze sefer* ‘which book’ to its position inside the most-embedded CP, or the link of *le-mi* ‘DAT-who’ to its position inside that CP.

As a further example, recall (18c), repeated below:

- (18) c. ? [et ma]₂ yadata [CP še-Rina zaxra [CP [mi-mi]₁ Dan lakax t₁ t₂]]?
ACC what knew.2SG that-Rina recalled from-who Dan took
‘[What]₂ did you know that Rina recalled [from whom]₁ Dan took t₂ t₁?’

The most-embedded clause in (18c) starts out as follows:

- (54) [TP Dan lakax [mi-mi] [et ma]]
Dan took from-who ACC what

The [iOp_{wh}] feature on the most-embedded Foc⁰ would then attract *mi-mi* (‘from-who’) to [Spec,FocP]:¹⁴

- (55) [FocP [mi-mi]₁ [TP Dan lakax t₁ [et ma]]]
from-who Dan took ACC what

Subsequently, [iOp_φ] on C⁰ attracts *et ma* (‘ACC what’) to [Spec,CP]:

- (56) [CP [et ma]₂ [FocP [mi-mi] [TP Dan lakax t₁ t₂]]]
ACC what from-who Dan took

Given the PIC, only *et ma* (‘ACC what’)—and not *mi-mi* (‘from-who’)—will be visible for computation outside of this CP. This is precisely what happens in (18c)—*et ma* (‘ACC what’) is moved successive-cyclically to the matrix [Spec,FocP]:

- (57) [FocP [et ma]₂ yadata [CP t₂ še-[FocP [TP Rina zaxra [CP t₂ [...]]]]]
ACC what knew.2SG that- Rina recalled

Note that *et ma* (‘ACC what’) is not attracted by the intermediate Foc⁰, because the intermediate clause is declarative (as evinced by the overt declarative complementizer, *še* ‘that’; see the discussion of (10) in §5.2.2). Instead, it is attracted by the intermediate C⁰; being at [Spec,CP], it is then accessible for movement to the matrix [Spec,FocP].

¹⁴See fn. 4 regarding superiority in Hebrew ditransitives.

Now recall (19c), repeated below—the ungrammatical counterpart of (18c), above:

- (19) c * [et ma]₂ yadata [CP [mi-mi]₁ Rina zaxra [CP še-Dan lakax t₁ t₂]]?
 ACC what knew.2SG from-who Rina recalled that-Dan took
 ‘[What]₂ did you know [from whom]₁ Rina recalled that Dan took t₂ t₁?’

In (19c), both *et ma* (‘ACC what’) and *mi-mi* (‘from-who’) “completely escape” the most-embedded clause, where they were both base-generated—in other words, they both appear overtly outside of the most-embedded CP. As discussed earlier, this implies that they both moved through the most-embedded [Spec,CP]; but since there is only one specifier for CP, this could not occur. The only remaining alternative is that one of them moved out of the most-embedded CP from a position strictly within it (i.e., within the complement domain of the most-embedded C⁰), therefore incurring a PIC violation.

The proposal therefore predicts the ungrammatical status of (19c).

Finally, note that the analysis predicts Nested Interrogatives with more than two wh-elements should be possible, as long as all but one of the wh-elements undergo clause-local wh-movement.¹⁵ This prediction is indeed borne out:

- (58) ? [et ma]₂ Rina šaxexa [CP mi₃ t₃ zaxar [CP [mi-mi]₁ Dan kibel t₁ t₂]]?
 ACC what Rina forgot who recalled from-who Dan received
 ‘[What]₃ did Rina forget [who]₃ t₃ recalled [from whom]₁ Dan received t₂ t₁?’

6. Odds and Ends

6.1. PIC and the Verb-Ph(r)ase

A putative problem for the account developed so far is the status of phases headed by a verbal projection.¹⁶ The analysis of superiority effects in §5.2.2 relied on the following assumption: at the point in the derivation where operator-features probe for wh-elements, the internal arguments of the lexical verb are either at their base positions, or at least stand in a hierarchical configuration that mirrors the configuration that they had at their base positions. The question is, how the existence of a phase-boundary at the verb-phrase level would affect this assumption.

In this section, I will examine the effects of such a phase-boundary on the predictions presented in previous sections (and in particular, on the aforementioned assumption), and show that in fact, there are no such effects—in other words, the existence of a verb-phrase level phase-boundary is immaterial to the current analysis.

¹⁵Thanks to an anonymous reviewer for pointing this out.

¹⁶The identity of the head of the verb-phrase phase, as well as the exact set of verbs for which phasehood would be triggered, is subject to much debate in the literature. Chomsky (2001) states that the VP-level phase is headed by little-*v*, and that only transitive and unergative verbs trigger (strong) phasehood (encoded as the distinction between *v**P and *v*P; Chomsky 2001). Fox (2002), Legate (2003), and Richards (2004, 2007a) show evidence that passive/unaccusative/raising verb-phrases constitute a phase, on par with transitive verb-phrases. Horvath and Siloni (2002) argue against the very existence of the little-*v* projection, but later propose that the lexical verb itself serves as the head of the verbal phase (Horvath and Siloni 2006).

The exact view that one chooses to adopt regarding the phasehood of the verb-phrase is not crucial to the current discussion, as will be shown below.

For concreteness, let us assume that unergative and transitive verb-phrases are selected by v^* , which heads a strong phase (this specific implementation follows Chomsky 2001, but as will be shown below, nothing ends up depending on a particular conception or distribution of the verb-phrase level phase).

If the internal arguments of the verb are enclosed within the v^*P phase, they will be inaccessible by the time C^0 probes for wh-elements—unless of course they have moved to the periphery of their phase (i.e., [Spec, v^*P]), as is commonly assumed.

A somewhat more subtle question concerns the accessibility of an internal argument to probing by Foc^0 . As noted by Mueller (2004) and Richards (2006), there are two variants of the *P(hase)I(mpenetrability)C(ondition)* currently “on the market”:

- (59) a. “PIC₁” (Chomsky 2000):
 In a phase α headed by H^0 , the domain of H^0 is not accessible to operations outside of α . Only H^0 and its edge are accessible to such operations.
- b. “PIC₂” (Chomsky 2001):
 If Z^0 is the next phase head up after H^0 , the domain of H^0 is not accessible to operations at ZP . Only H^0 and its edge are accessible to such operations.

As argued by Richards (2006), the only empirical difference between PIC₁ and PIC₂ is their predictions regarding the accessibility of the domain of H^0 to probing from outside of the HP phase in the derivational interval before Z^0 (the next phase head up) has been merged.

In the following sub-sections, I will consider the predictions made by both variants of the PIC, with respect to Nested Interrogatives in Hebrew.

6.1.1. A wh-Subject and a Lower wh-Element

Consider a configuration involving a wh-subject, in addition to another, hierarchically lower wh-element. Such a configuration is attested in (9a), repeated below:

- (9) a. [et ma]₂ Dan šaxax [CP [mi]₁ t₁ axal t₂]?
 ACC what Dan forgot who ate
 ‘[What]₂ did Dan forget [who]₁ t₁ ate t₂?’

Since *axal* (‘ate’) is a transitive verb, the embedded clause must contain a v^*P , and the wh-subject *mi* (‘who’) must originally be merged as a specifier of that v^*P . The object wh-element, *et ma* (‘ACC what’), eventually moves out of the embedded CP entirely, meaning it passes through the embedded [Spec, CP]. As discussed above, regardless of which version of the PIC is adopted, the accessibility of *et ma* (‘ACC what’) to probing by C^0 entails that it first must move to [Spec, v^*P]. This means v^*P necessarily has more than one specifier.¹⁷

As shown by Richards (1997, 2001), movement to multiple specifiers of the same head observes a “tucking-in” topography—in other words, a moved phrase will form a new specifier in between the head of the targeted projection and its closest existing specifier (if one exists). Note that this conclusion obtains even if one adopts the view that all operations within a phase take place simultaneously at the phase level (Chomsky 2001, to appear)¹⁸—since Richards’ (1997, 2001) argument is based on locality considerations, rather than the timing of movement operations.

If it were the case that locality considerations—such as “tucking-in”—could be obviated by the simultaneity of operations at the phase level, one would not expect superiority effects to show up between two *wh*-arguments both of which are base-generated below the ν^* P-phase in an interrogative clause. This is because, by the time the interrogative periphery probes, the two *wh*-elements would be located in multiple-specifiers of the relevant ν^* P—where, given the aforementioned simultaneity, they could presumably appear in either hierarchical order. However, such superiority effects are in fact attested:¹⁹

- (60) a. [To whom]₁ did Mary [ν^* P mention t₁ that John would buy what]?
 b. ?? [What]₁ did Mary [ν^* P mention to whom that John would buy t₁]?

This demonstrates that even if phase-level simultaneity is assumed, it cannot subsume all of the phenomena meant to be handled by locality considerations, of the kind addressed by Richards’ (1997, 2001) arguments.

Assuming that a head performs lexical selection prior to performing *Agree*/search—a likely assumption, given the more stringent locality conditions on lexical selection, compared to *Agree*/search (see Matushansky 2006)—the presence of an external argument will derivationally precede movement of the *wh*-element to [Spec, ν^* P]. Thus, “tucking-in” would predict that the object would be moved to a specifier position in between the external argument and the ν^* head:

¹⁷It is more than somewhat suspicious that while CPs with single-specifier restrictions are cross-linguistically quite common, the same behavior for ν^* P is rare or impossible; in fact, any language that allows extraction in a configuration such as (i), below, must allow for multiple ν^* P specifiers:

- (i) Who₂ did John₁ [ν^* P t₁ say that Mary met₂]?

Since the verb *say*, in (i), has an external argument, there must be a second specifier of ν^* P to enable movement of *who* out of the ν^* P phase.

Whether this asymmetry between CPs and ν^* Ps is to be taken as a counter-argument to the phasehood of little-*v*—or alternatively, as a counter-argument to the single-specifier restriction—is beyond the scope of this paper.

¹⁸Thanks to an anonymous reviewer for pointing out this concern.

¹⁹Note that, abstracting away from *Pair/Tuple-List* questions, there is nothing wrong with extraction of the kind shown in (60b):

- (i) What did Mary [ν^* P mention to Bill that John would buy t₁]?

Crucially, this state of affairs preserves the hierarchical relations between wh_1 (the external argument) and wh_2 (the lower wh-element): wh_1 still c-commands wh_2 .

Thus, a Foc^0 or C^0 head probing for wh-elements from outside of this v^*P phase would be confronted with the same hierarchical relations (between wh_1 and wh_2) as it would if the strong phase had not been there at all—regardless of which of the two versions of the PIC is adopted; one might call this the property of “phase transparency”. Hence, for cases involving a wh-subject and a lower wh-element, a strong phase at the VP level makes no difference with respect to the predictions made by the current proposal.

6.1.2. Two Internal wh-Arguments

In addition to the configuration discussed in §6.1.1, there are also cases of two wh-elements which originate as internal arguments, both of which undergo wh-movement. Recall (18a), repeated below:

- (18) a. [eyze sefer]₂ šaxaxta [CP [le-mi]₁ Dan šalax t₁ t₂]?
 which book forgot.2SG DAT-who Dan sent
 ‘[Which book]₂ did you forget [to whom]₁ Dan sent t₂ t₁?’

Both internal arguments have observably escaped the verb-phrase of *šalax* (‘sent’). While *eyze sefer* (‘which book’) has moved all the way out of the embedded CP, *le-mi* (‘DAT-who’) has remained within it. Given the current proposal, *le-mi* (‘DAT-who’) has moved to the embedded [Spec,FocP].

Here, the two versions of the PIC diverge slightly (though, as will be shown, without significant consequence). Given PIC₁ (59a), both Foc^0 and C^0 cannot probe into the complement domain of v^* . The formulation of PIC₂ (59b), on the other hand, entails that the v^*P phase is not “closed off” until the next phase head (namely, C^0) is merged. Thus, Foc^0 is able to probe into the complement domain of v^* .

It may seem that the different versions of the PIC therefore give us different predictions regarding which of the wh-elements in (18a) need to relocate to [Spec, v^*P]. Under PIC₁, both wh-elements need to move to [Spec, v^*P]. Under PIC₂, it would appear that only the wh-element that moves to [Spec,CP] needs to move to [Spec, v^*P], since Foc^0 can probe all the way into v^*P .

However, such a conclusion would be mistaken. Consider what happens if only one of the internal arguments moves to [Spec, v^*P]:

Note that movement to $[\text{Spec}, v^*P]$ is a form of successive-cyclicity; it does not render the wh -feature on the wh -element interpretable. Thus, in the configuration depicted above, probing by Foc^0 would result in wh_1 , the wh -element that has been moved to $[\text{Spec}, v^*P]$, being attracted and moved to $[\text{Spec}, \text{Foc}P]$. That is because wh_1 constitutes the closest syntactically active wh -element. Once at $[\text{Spec}, \text{Foc}P]$, wh_1 would be inactive, and thus move no further. As discussed earlier, C^0 could not probe into v^*P , and therefore wh_2 would not move either—meaning a derivation in which only one of the internal arguments has moved to $[\text{Spec}, v^*P]$ could never give rise to wh -movement of both internal arguments—and as a result, would never give rise to a Nested Interrogative construction.

Therefore, every derivation involving wh -movement of more than one internal argument necessarily involves both of them moving to $[\text{Spec}, v^*P]$. Given “tucking-in”, this would give rise to the following configuration:

Crucially, the representation in (63) shares with (61) the property of “phase transparency”—in other words, the v^*P phase preserves the hierarchical relations between wh_1 and wh_2 , that existed at their base positions.

Once again, we have arrived at the conclusion that whether or not a VP level-phase exists (and whether one adopts PIC1 or PIC2), a higher Foc^0 or C^0 head will be faced with the same hierarchical

configuration when it probes—and therefore, the predictions discussed in earlier sections stand, regardless of whether or not such a phase boundary exists.

6.2. wh-Adverbials

In dealing with superiority effects in Hebrew Nested Interrogatives (sections §3.1 and §5.2.2), only *wh*-elements that function as arguments of the verb were considered. The behavior of *wh*-adverbials, on the other hand, might appear problematic:

- (64) a. * [eyx]₂ Dina tahata [[eyze asir]₁ [TP t₁ nimlat me-ha-kele t₂]]?
how Dina wondered which prisoner escaped from-the-prison
- b. ? [eyze asir]₂ Dina tahata [[eyx]₁ [TP t₂ nimlat me-ha-kele t₁]]?
which prisoner Dina wondered how escaped from-the-prison
‘[Which prisoner]₂ did Dina wonder [how]₁ [TP t₂ escaped from prison t₁]]?’

Prima facie, it seems that the superiority pattern observed in §3.1 (and analyzed in §5.2.2) is reversed: the *wh*-adverbial moves clause-locally, whereas the subject moves out of the embedded clause, to the matrix periphery.

However, this is only a reversal of the aforementioned superiority pattern on the assumption that the subject originates in a hierarchically higher position than the *wh*-adverbial. It has been argued (for various *wh*-adverbials in various languages) that some *wh*-adverbials can be base-generated in clause-peripheral operator position, as opposed to arriving there via \bar{A} -movement.²⁰ If this is indeed the case regarding *eyx* ‘how’ in Hebrew, then the superiority pattern in (64) is to be expected. The *wh*-adverbial would be base-generated in [Spec,FocP], which was independently established as an operator position in Hebrew (see §5.1.2), leaving only [Spec,CP] available for the *wh*-subject—facilitating its subsequent movement to the matrix periphery:

- (65) ? [eyze asir]₁ Dina tahata [CP t₁ [_{FocP} eyx [_{TP} t₁ nimlat me-ha-kele]]]?
 which prisoner Dina wondered how escaped from-the-prison
 ‘[Which prisoner]₁ did Dina wonder [CP how t₁ escaped from prison]?’

If this property of *wh*-adverbials is indeed the relevant characteristic, the prediction is that *wh*-elements that are adjuncts (as opposed to arguments), but are not *wh*-adverbials, would pattern with verbal arguments in terms of superiority. This is indeed the case:

- (66) a. ? [be-eyzo universita]₂ Dan šaxax [CP t₂ [_{FocP} [mi]₁ [_{TP} t₁ lamad t₂]]]?
in-which university Dan forgot who studied
‘[In which university]₂ did Dan forget [_{CP} [who]₁ studied]?’
b. * [mi]₂ Dan šaxax [CP t₂ [_{FocP} [be-eyzo universita]₁ [_{TP} t₁ lamad t₂]]]?
who Dan forgot in-which university studied

²⁰See [Collins \(1991\)](#) regarding *how come* in English; [Bromberger \(1992\)](#) on *why* in English; [McCloskey \(2002\)](#) regarding *cén fáth* ‘what reason’ and *cad chuige* ‘why’ in Irish; [Boskovic \(2000\)](#) and [Rizzi \(1990\)](#) regarding *pourquoi* ‘why’ in French; [Rizzi \(1999\)](#) on *come mai* ‘how come’ and *perche* ‘why’ in Italian; and see [Ko \(2005\)](#) for a comprehensive and insightful discussion of the aforementioned sources.

Thus, it seems that the apparent exception posed by cases such as (64a–b) is the result of the unique properties of wh-adverbials—and specifically, the possibility of such wh-adverbials being base-generated directly in operator position.

7. Conclusion

The paper began by surveying the phenomena exhibited by the Nested Interrogative construction in Hebrew—namely, the superiority pattern, and the distribution of wh-island effects.

I then proposed an analysis in which the feature relevant to wh-movement in Hebrew is located on a head in the left periphery that is lower than C^0 . This was independently motivated by the existence of *Sub-Complementizer Topicalization*, which is a case of \bar{A} -movement in Hebrew that targets a position below the overt complementizer (as shown in section §4). Despite the fact that in this analysis, CP is not the target of overt wh-movement, its single specifier can still be utilized for successive-cyclic wh-movement, and is the only way to move to positions strictly outside of CP.

This proposal was shown to derive both the superiority pattern and the distribution of wh-islandhood effects. It was also shown that the predictions made by this proposal are unaffected by the existence (or lack thereof) of a strong phase at the VP level (§6.1). Furthermore, the apparently deviant behavior of wh-adverbials with respect to superiority was shown to follow from the assumption that at least certain wh-adverbials can be base-generated in operator position—an assumption that has significant cross-linguistic merit (§6.2).
