

The interpretation of external arguments

Jim Wood and Alec Marantz

1. Introduction

The striking parallels across languages in the syntactic expression of “argument structure” broadly construed has led within generative grammar, at least since Generative Semantics, to generative theories that demand a kind of transparent reflection of argument structure in underlying syntactic representations. This trend is reflected in approaches oriented around thematic roles, such as those that adopt some version of UTAH, as well as event-structure oriented approaches like that in Ramchand 2008 in which, in a sense, event structure is underlying syntactic structure. An alternative approach attributes the relative uniformity of the expression of argument structure to the principles that interpret syntactic structure semantically; here, syntax is truly autonomous, with the atoms of syntactic representations and their relations carrying no semantic values. On this alternative approach, we might expect that the same meanings could be expressed by different syntactic structures and that the same syntactic structures might express different meanings.

Recent work from Myler and Bruening illustrate this approach in different though related domains. Myler (2014) argues that the expression of possession in predication (as in “I have a book”) varies cross-linguistically in such a way that the same meanings are constructed by different syntactic processes in different languages, without being related to a single syntactic structure. Bruening (2010) argues in the same vein that the double object and the *to*-dative expression of transfer of possession in English involve different syntactic structures, not transformationally related structures. (Here he follows a long tradition in the literature but provides a contemporary demolition of the alternative proposals.)

While Myler and Bruening support the autonomy of syntax by demonstrating that syntactic structures may be semantically ambiguous and semantic structures may find alternative syntactic representations, in this chapter we will extend the argument to the inventory of syntactic heads. We will argue that syntactic heads crucially involved in the interpretation of argument structure – heads like *v*, voice, *p* and *appl* – are subject to contextual alloosemy at the semantic interface such that each such head may have a particular range of meanings, including a null (expletive) meaning, depending on the syntactic context. Once syntactic heads are absolved from the necessity of carrying certain features relevant to their interpretation explicitly – when the features are rather computed contextually at the point of semantic interpretation – we can develop a sparse inventory of functional heads for the syntax.

For example, in theories that separate a verbalizing category head *v* from the verbal root, the little *v* node is observed to vary in interpretation across verb categories, in particular alternating between what might be labeled v_{BECOME} for inchoative sentences like “the door opened” and v_{DO} (or v_{CAUSE}) for transitive sentences like “John opened the door.” The alternation here is a reflection of Burzio’s Generalization: external argument and transitivity lead to the v_{DO} interpretation and no external argument and intransitivity lead to the v_{BECOME} interpretation. If the interpretation of the *v* correlates with the syntax, then there is no motivation to include a syntactic feature related to the difference in interpretation, over and above any syntactic features related to the syntactic projection of an external argument and syntactic transitivity.

In this chapter, we present an account of the heads that add participants to events. Within current theories, these heads are usually identified as voice, *appl*, and prepositions, as well as little *v* for some linguists, where the causative little *v* head might introduce an agent or causer. We will follow Pylkkänen (2008), Harley (2013) and Legate (2014) among others, in arguing

that little *v* does not, by itself, introduce an argument, so our account will focus primarily on the voice, *appl*, and prepositional heads. The empirical focus of the chapter revolves around Icelandic figure reflexives, Japanese adversity causatives, and possessor raising constructions.

The chapter is organized as follows. In section 2, we lay out our basic proposal, outlining the syntactic and semantic features of argument-introducing heads. In section 3, we present an analysis of Icelandic figure reflexives, which illustrates one basic process that will be crucial to the analysis of possessor raising and Japanese adversity causatives. In section 4, we develop the account of Japanese adversity causatives. This will involve an analysis of predicate possession, the internal argument of change-of-state (anti)causatives, and possessor raising. Section 5 concludes.

2. The proposal

We begin by making a distinction between little *v*, on the one hand, and voice, *appl* and prepositions, on the other. As we will discuss in more detail in section 4, little *v* has the syntactic function of verbalizing category-neutral roots, and serves as the semantic locus for a variety of interpretive processes which will be discussed throughout. What little *v* does not do is introduce argument DPs syntactically; nor does it serve as the semantic locus for the thematic interpretation of DPs. Morphologically, however, the spellout of little *v* can be sensitive to the presence of an external argument. For example, in languages like Japanese, the causative-inchoative alternation is often marked with a (“lexical”) “causative” affix on the transitive variant. As we will discuss further below, this “causative” affix does not always imply causative semantics. What the morphology is telling us, in this case, is not that the semantics involves causativity, but that the syntax involves an external-argument introducing voice head in a

transitive construction. That is, the causative suffix is the contextually-determined spellout of little *v* in the context of an external-argument-introducing voice head.

In terms of argument-introducing heads, then, we are left with essentially five potentially distinct heads:

- (1) a. voice, which introduces the external arguments of verb phrases (often agents)
- b. low *appl*, which introduces an extra argument related to a DP
- c. little *p*, which introduces the external argument of prepositional phrases (figures)
- d. prepositions, which introduce non-core arguments in a manner syntactically distinct from high *appl*
- e. high *appl*, which introduces a non-core argument

We will propose that these five heads can be reduced to one single argument introducer, which we will refer to as *i*^{*}, in distinct syntactic contexts. The differences between the apparently different uses of *i*^{*} stem from rules that are sensitive to the syntactic context in which this head occurs.

Our proposal is thus that from a syntactic perspective, there is one argument-introducing head, which is unspecified categorially and selects for a syntactic constituent of category D (selection for D encodes the “argument introducing” property that characterizes these heads). Following Bruening (2012), we annotate selectional features in brackets, so $P_{[S:D]}$ is a head of category P that selects (S) for a constituent of category D. Since *i*^{*} is categorially unspecified, it does not start out with a categorial feature, but is rather something like $\{[CAT: _], [S:D]\}$, where the underscore indicates an unvalued CAT(egory) feature; *i*^{*} is simply a convenient notation for this feature bundle. We should note immediately that the selectional feature [S:D] is not to be

understood as a necessary condition on Merge, as will be clear below; it is a feature that can, but need not, trigger Merge with a constituent of category D. In the context of the present study, it would be descriptively accurate to say that a selectional feature cannot be checked until the categorial feature is valued. In cases where the selectional feature is checked and the categorial feature is unvalued, the categorial feature will automatically get the value “P”. This, as we will see, is how prepositions are built.

There are essentially three factors that interact to determine the syntactic and semantic properties of i^* . First, i^* can merge with a variety of syntactic categories, so its interpretation can be read off of its structural position. Second, the categorial feature of i^* may be valued by the categorial feature of the first or the second constituent it merges with. Third, lexical roots may adjoin to i^* ; when they do, they will affect the interpretation of i^* (as well as certain syntactic properties of i^* , as we will see).

The ‘*’ notation on i^* indicates a crucial syntactic property of this head, one which does not follow automatically from its other syntactic and semantic functions. Essentially, i^* closes off the extended projection of the first constituent it merges with. If that constituent is a lexical root, it closes off the extended projection of the lexical root (to the extent that lexical roots have extended projections; nothing in the present paper hinges on answering the question of whether roots may take arguments or otherwise project). If that constituent is an XP, then it closes off the extended projection of that XP. We will notate this by projecting the ‘*’ only onto the node that immediately dominates i^* . Although this is stipulative, it is definitional-stipulative, telling us something about the basic properties of the system. We leave it to future research to determine whether the stipulation would follow directly from a slightly different general architecture of grammar.

As a final note on notation, we will generally label phrasal constituents as XP in the familiar way, without necessarily committing to the idea that phrasal nodes are actually labeled in this way by the grammar in any sense that matters for the syntax. However, c-selection does require the notion of a head, and thus at least the determination of an asymmetry between merged constituents. Much of the work apparently done by phrasal constituent labeling here could be recast in terms of structural conditions revolving around the head (cf. Collins 2002).

Let us now illustrate how these assumptions derive the basic interpretations of argument-introducing heads. First, we can define the basic heads -- little p, voice and low appl -- as follows:

- (3) a. Little p (figures): Bare i^* that merges with a PP.
- b. Voice (agents): Bare i^* that merges with a vP.
- c. Low appl (possessors): Bare i^* that merges with a DP.

When i^* merges with these constituents, its categorial feature is valued to match that of its complement. So when i^* merges with a vP, it becomes $\{[CAT:v],[S:D]\}$. Since it is a head merging with an XP, it will be the label of the resulting constituent: essentially $v^*[S:D]$. It projects its selectional feature, so that the newly formed $v^*P[S:D]$ c-selects for something of category D. Note that this system places voice within the extended projection of v; the * notation indicates that voice also closes this projection.

The interpretive differences between what were formerly understood as distinct heads are now understood as contextually determined interpretation rules. We illustrate this for agents and figures in (4) (we return to possessors in section 4).

- (4) a. $\llbracket i^* \rrbracket \leftrightarrow \lambda x \lambda s. \text{FIGURE}(x,s) / \text{___} \text{ (locative PP)}$
- b. $\llbracket i^* \rrbracket \leftrightarrow \lambda x \lambda e. \text{AGENT}(x,e) / \text{___} \text{ (agentive vP)}$

Voice, little *p* and low *appl*, then, are three distinct “uses” of the same syntactic head. We will see further below that these heads are indeed syntactically and semantically similar in a way that supports their unification.

(Big) *P* and high *appl* are different, in that they seem to introduce their own thematic semantics in a way that does not depend on the semantics of the element they attach to. According to our proposal, this is because *P* and high *appl* are the names we give to i^* with a lexical root adjoined to it. In the cases of interest here, the lexical roots of prepositions adjoin to i^* to form a DP-selecting preposition. When this i^* merges with a DP, its selectional feature may or may not be checked. When it is checked, the categorial feature of i^* is automatically valued as *P*. This is, then, a configurational definition of a preposition: a preposition is an i^* that checks its selectional feature without valuing its categorial feature.¹ The lexical semantics of the overall preposition stems from the root. They can be determined by the root directly, or else as contextually-specified interpretations of i^* in the context of the root. Thus, *in* is different from *on* because the root $\sqrt{\text{IN}}$ has or conditions different semantics from the root $\sqrt{\text{ON}}$ (e.g. container vs. surface). The structure of a *pP* small clause such as *the car on the road* is shown in (5).

(5)

¹ We might then take *of* in its semantically vacuous uses to be an instance of i^* without a root adjoined to it merging with a DP and checking its selectional feature. We set aside, for now, a more detailed investigation of this possibility.

First, $\sqrt{\text{ON}}$ adjoins to i^* . This i^* merges with a DP *the road*, satisfying the selectional [S:D] feature; at this point, the categorial feature of i^* is valued as “P”, so it projects a PP. Then, another i^* merges with this PP, which values i^* ’s categorial feature as “p”, resulting in $p_{[S:D]}$. Since the selectional [S:D] feature has not been checked, the resulting constituent is $p^*P_{[S:D]}$, i.e. a pP that c-selects a constituent of category D. Finally, the DP *the car* merges with the $p^*P_{[S:D]}$ to form a pP. The interpretive rule in (4a) applies, and *the car* is interpreted as a figure of the spatial relation introduced by *on*.

In general (with a principled exception to be discussed below), what the i^* head does is merge with X, and then with Y, and then assign to Y the thematic role implied by X. If X is a lexical root, then it assigns to Y the role implied by that root. In (5) above, the lower i^* merges with $\sqrt{\text{ON}}$ and then a DP and assigns to the DP the role implied by $\sqrt{\text{ON}}$ (so the DP is interpreted as a surface).² The higher i^* merges with a PP and then a DP, and assigns to the DP the role implied by the PP (namely, the figure role implied by the overall spatial semantics of the pP, i.e., the external argument of the pP).

This account of prepositions leads us directly to our account of high appl. High appl is like a root-adjoined i^* in that the θ -role it ultimately assigns to a DP (in its specifier) is not implied by the vP semantics. For example, a vP like *hold the bag* may imply an agent before an agent is projected syntactically just by virtue of what it means to hold a bag. But the same would not hold for a beneficiary; there may be a beneficiary of a bag-holding event, but there is nothing about bag-holding that in itself implies the presence of a beneficiary. So when a high appl merges with a vP, it cannot be the case that the θ -role it assigns comes from that vP. Instead, the range of θ -roles available to a high appl tends to be drawn from the kinds of θ -roles that can also

² Here we follow the insights of Svenonius (2003, 2007) in assuming that in figure-ground oppositions (Talmy 1985), figures are true external arguments, analogous to agents in verb phrases, whereas grounds get a variety of interpretations, just like themes in verb phrases.

be introduced by prepositions: beneficiaries (English *for*), maleficiaries (English *on*), locations (English *in*), etc. Finally, high appl differs from voice in that it does not “close off” the vP projection; by merging first with a root, it closes off the projection of the root, and does not “project” its closing off star to the appl head it creates. Essentially, a high applP is just like a vP; anything that can select for a vP can select for a high applP. There is no necessary categorial difference between a high applP and a vP (Harley 2013:50,fn.23).

Following recent work (Acedo Matellán 2010; Haselbach and Pitteroff 2014), prepositions can be like other lexical categories in consisting of a category-neutral root and a category-determining functional head. We want to say that adjoining a root to i^* can ultimately lead to a P and a PP. But as noted above, this happens when the root-adjoined i^* checks its selectional feature by merging with DP. Another possibility is that i^* does not check its selectional feature on first merge, but instead values its categorial feature. If the root-adjoined i^* merges with a vP, its categorial feature is valued as “v” and its selectional feature is projected onto the resulting constituent. However, since this is the second merge, the resulting vP is just $vP_{[S:DP]}$, not $v^*P_{[S:DP]}$. The θ -role implied by the root will then be assigned not to the vP, but to the DP specifier (a conclusion which follows from how the compositional semantics works, as will be shown below). We can now distinguish what are traditionally called prepositions and high appl heads in the following way:³

- (6) d. Big P (prepositions): root-adjoined i^* with selectional feature checked by complement.
- e. High appl (affectees): root-adjoined i^* with selectional feature not checked by complement.

³ In principle, a low appl could also be root-adjoined, as long as its DP complement values its categorial feature instead of checking its selectional feature. We leave this possibility for future research.

High appl, then, instantiates the most complex of the i^* configurations. It takes three instances of merge to build it: merge with a root that determines the thematic role, followed by merge with a vP that determines its category, and finally merge with a DP that ultimately bears the thematic role determined by the root.

Consider how this derives the similarities between a beneficiary PP and a beneficiary high appl. A beneficiary PP like *for Mary*, adjoined to vP in the sentence *John held the purse for Mary*, would have the structure in (7).

The PP *for Mary* is formed in the same manner as the PP *on the road* was in (5) above. This constituent then adjoins to the vP *hold the purse*. Next, the agent is introduced: i^* merges with vP, valuing its categorial feature as v, and projects a $v^*P_{[S:D]}$, i.e. a verb phrase structure that c-selects for a DP. The external argument DP *John* merges with this structure, resulting in a complete v^*P .

High appl is just like the preposition *for* except that instead of merging with DP and then vP, it merges with vP and then DP. In the present system, the difference stems from when the selectional feature of i^* is checked, which in turn reflects how the categorial feature is valued. The structure is illustrated in (8).

(8)

In this structure, i^* merges first the lexical root. Second, it merges with a vP , valuing its categorial feature as v , and projecting a $vP_{[S:D]}$. Finally, the selectional D feature is checked by merging $vP_{[S:D]}$ with the DP *Mary*. The external argument is added to this vP in the same manner as in (7).

Semantically, (7) and (8) yield the same results. We write i^*_{FOR} as an abbreviation for the i^* head with the root $\sqrt{\text{FOR}}$ adjoined to it. We assume that it has the semantics in (9), and the vP has the semantics in (10). We write vP_1 for the lower instance of vP , and vP_2 for the higher instance.

$$(9) \quad \llbracket i^*_{\text{FOR}} \rrbracket = \lambda x \lambda e. \text{BENEFICIARY}(x, e)$$

$$(10) \quad \llbracket vP_1 \rrbracket = \lambda e. \text{hold}(\text{the purse}, e)$$

Given this, when i^*_{FOR} merges with the DP first, and then the vP , as in (7), the result is as in (11) (see Wood 2015:22--26 for definitions of the compositional mechanisms invoked below):

$$(11) \quad \text{a. } \llbracket pP \rrbracket = \lambda e. \text{BENEFICIARY}(\text{Mary}, e) \quad (\text{by Functional Application})$$

b. $\llbracket vP_2 \rrbracket = \lambda e. \text{hold}(\text{the purse}, e) \ \& \ \text{BENEFICIARY}(\text{Mary}, e)$ (by *Predicate Conjunction*)

When i^*_{FOR} merges with the vP first, and then the DP, as in (8), the result is as in (12).

(12) a. $\llbracket vP_{[S:DP]} \rrbracket = \lambda x \lambda e. \text{hold}(\text{the purse}, e) \ \& \ \text{BENEFICIARY}(x, e)$ (by *Event Identification*)

b. $\llbracket vP_2 \rrbracket = \lambda e. \text{hold}(\text{the purse}, e) \ \& \ \text{BENEFICIARY}(\text{Mary}, e)$ (by *Functional Application*)

Both ways of combining i^*_{FOR} with a DP and a vP yield the same semantic representation, as can be seen in (11b) and (12b).

In sum, our proposal involves one argument introducing head, varying in terms of what it takes as a complement, and whether or not a root is adjoined to it. Now that we have introduced the basic layout of the system we propose, we turn to the empirical focus of the article, which provides support for the basic architecture that we are defending, one where a relatively autonomous syntax is subject to specific interpretive rules at the interfaces with semantics and morphophonology, generating apparent mismatches between the first-merged positions of arguments and the syntactic loci that determine their thematic interpretation. The general picture will provide support for the view outlined here, that voice, little p and low appl are syntactically identical, semantically identical (in that their interpretation is conditioned by the semantics of the constituent they attach to), and different from P and high appl only in the absence of a lexical root adjoined to them.

3. Voice and p: Icelandic figure reflexives

In Icelandic figure reflexives, a thematic “figure” role is introduced inside the pP complement of v, and saturated by a DP in SpecvoiceP. The external argument in figure reflexives may also receive from the voice head an agent role in addition to the figure role.

(13) $[_{\text{voiceP}} \text{Bjartur} \ \text{voice} [_{\text{VP}} \text{squeeze} \ [_{\text{pP}} \text{FIGURE through the crowd}]]]$

An Icelandic figure reflexive is illustrated in (16), along with the bracketing to indicate its basic syntactic structure (sticking to labels like “voice” and “p” for the moment).

- (16) $[_{\text{voiceP}} \text{Bjartur} \quad [_{\text{VP}} \text{tróð} \quad [_{\text{pP}} \text{st} \quad \text{gegnum} \quad \text{mannþröngina} \quad]]].$
 $[_{\text{voiceP}} \text{Bjartur.NOM} \quad [_{\text{VP}} \text{squeezed} \quad [_{\text{pP}} \text{-ST} \quad \text{through} \quad \text{the.crowd} \quad]]]$
 ‘Bjartur squeezed through the crowd.’

The point of interest raised by the analysis of Icelandic figure reflexives stems from the following three considerations:

- (i) *Bjartur* in (16) is interpreted as though it has two θ -roles, “agent” and “figure”, the latter role originating inside the pP;
- (ii) *Bjartur* is an external argument externally merged in SpecvoiceP (i.e. these are not unaccusative constructions);
- (iii) There are no reflexive morphemes in the structure.

These claims are defended at length in Wood (2014, 2015), but we will provide a brief overview here. (i) can be appreciated by comparing (16) with the sentences in (17).

- (17) a. Bjartur tróð blýöntunum í pokann.
 Bjartur.NOM squeezed the.pencils.DAT in the.bag
 ‘Bjartur squeezed the pencils in the bag.’
- b. Bjartur tróð sér gegnum mannþröngina.
 Bjartur.NOM squeezed REFL.DAT through the.crowd
 ‘Bjartur squeezed himself through the crowd.’

In (17), *Bjartur* is no longer interpreted as the “figure”, because there is another DP that bears this role: the pencils in (17a) and the reflexive pronoun in (17b). When the lower DP is gone, as in (16), *Bjartur* is understood as bearing the role that the lower DP bears in (17).

As for (ii), that *Bjartur* is externally merged in SpecvoiceP is shown by a number of considerations; for example, the sentence in (16) can be passivized, as illustrated in (18).

(18) Það var troðist gegnum mannþröngina.

EXPL was squeezed-ST through the.crowd

‘There was squeezing through the crowd.’

Impersonal passives in Icelandic diagnose the presence of an external argument interpreted as an agent (Sigurðsson 1989:315-321, Thráinsson 2007:266-269). This shows that *Bjartur* in (16) is externally merged in SpecvoiceP, and gets an agent role in addition to a figure role.⁴

Turning to (iii), unlike (17b), there is no reflexive morpheme in (16). The *-st* morpheme is not, by itself, reflexive, and there is no evidence that it may bear a θ -role. The reflexive reading of some *-st* verbs is an old and interesting problem, but in general, “reflexive verbs” are expressed with separate reflexive pronouns, as in (17b). This even holds for “inherent” reflexive verbs (such as *hegða sér vel* ‘behave oneself’), which can only take a reflexive object, and “natural reflexives” like *raka sig* ‘shave oneself’, which most naturally take a reflexive object. Note that these SE-reflexives stand in opposition to complex, “self” reflexives in the familiar way (see Sigurjónsdóttir 1992; Wood 2015:41). The *-st* morpheme ultimately does contribute to the reflexive meaning of (16), but it cannot be maintained that *-st* can in any way bear a θ -role or be “co-indexed” with a DP.

⁴ A reviewer points out that impersonal passivization is not a good diagnostic for external-argumenthood or agency in Dutch, citing Den Dikken (2010:50-51). As far as has been determined, the diagnostic does hold for Icelandic; see Sigurðsson (1989:315-321) for extensive discussion of the agency effect, and Thráinsson (2007:266-269) for a review of the relevant facts. Note that if Maling & Sigurjónsdóttir (2002, et seq.) are correct, impersonal passives might for some speakers actually be impersonal active constructions. Crucially, however, figure reflexives are passivizable for all speakers. See Wood (2015: 179ff.) for a battery of further tests pointing to the conclusion that figure reflexives are agentive; in fact, every known agentivity test supports this conclusion. Thus, even if Icelandic turned out to be like Dutch in that impersonal passivization does not unambiguously diagnose agentivity, there is independent evidence that the subject of figure reflexives is agentive.

Wood (2014, 2015) proposes that *-st* is an argument expletive (Schäfer 2008; Sigurðsson 2012; Alexiadou et al. 2015): it merges in an argument position syntactically (before cliticizing to the verbal complex), but is effectively invisible in the semantics. The consequence of this “semantic invisibility” depends on which specific position *-st* occupies. For example, suppose it merges in the external argument position, as in (19b).

- (19) a. *María opnaði hurðina.* [_{v*P} Mary *i** [_{vP} opened the door]]
 Mary.NOM opened the.door.ACC
 ‘Mary opened the door.’
- b. *Hurðin opnaðist.* [_{v*P} *-st i** [_{vP} opened the door]]
 door.the.NOM opened-ST
 ‘The door opened.’

In (19a), the DP *María* merges as the external argument of *open the door*. In this case, *i** may be interpreted as introducing an agent θ -role, which will be saturated by (the denotation of) *María*. In (19b), *-st* merges in this same position, which satisfies the selectional D feature introduced by *i**. But in the semantics, since *-st* is basically invisible, the consequence is that *i** may not introduce an external θ -role. The result is an anticausative interpretation: a door-opening event is asserted, but no external cause or agent is expressed. (We will elaborate on the interpretation of the causative/inchoative alternation in section 4.2 below.)

There are, then, at least two allosemes -- contextually conditioned interpretations -- of *i**, as illustrated in (20). (Note that we use double arrows when an interpretation is inserted into a terminal node post-syntactically, and equal signs when a denotation computed on a nonterminal node by some compositional mechanism.)

- (20) a. $\llbracket i^* \rrbracket \leftrightarrow \lambda x \lambda e. \text{AGENT}(x,e) / \text{---} (\text{agentive vP})$

b. $\llbracket i^* \rrbracket \leftrightarrow \lambda x. x$

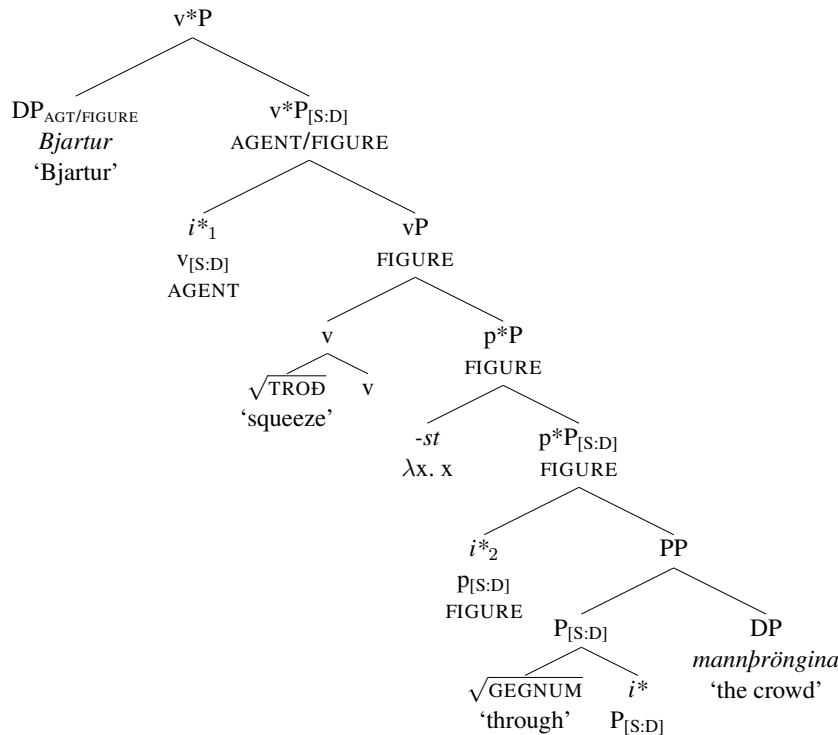

(20a) introduces an agent role, while (20b) is “expletive” voice: it simply takes the denotation of its complement vP and returns that same denotation. (We will see below that the availability of an expletive interpretation is a general option for, and perhaps even a defining property of, bare i^* .) The choice between (20a) and (20b) is made in the semantics, after the syntactic structure is built and sent to spellout. If the vP is interpreted as the sort of event that has an agent, (20a) will be chosen. If the vP is interpreted as the sort of event that happens on its own (see Haspelmath 1993; Schäfer 2008; Alexiadou et al. 2015:ch3), (20b) will be chosen. An event like “open the door” can be construed in either way, so both of the alloemes in (20a) and (20b) are available. Other events, such as events built with verbs like ‘murder’, can only be construed as agentive, so only (20a) will be available. Still other events, such as those built with verbs like ‘blossom’, can only be construed as happening on their own, so only (20b) will be available.

Importantly, certain structures are only compatible with one alloeme or another. For example, when there is a DP external argument, (20b) will be impossible unless there is some other mechanism for integrating that DP semantically into the interpretation of the vP (see Wood 2015: 143ff., and also section 4 below). Similarly, when an expletive element such as Icelandic *-st* in the external argument position, (20a) will be impossible unless there is some other mechanism for saturating the agent role in the semantics (see Wood 2015: 259ff.). Thus, if we choose an event that requires (20a), but try to put *-st* in the external argument position, the result is ungrammatical:

- (21) * Maðurinn myrtist. $\llbracket_{v^*P} -st i^* \llbracket_{vP} \text{murdered the man} \rrbracket \rrbracket$
the.man.NOM murdered-ST
INTENDED \approx ‘There was an event of murdering the man.’

The reason that i^* cannot introduce an external θ -role is that doing so would violate “Full Interpretation” (Harley 2011); the external θ -role would not be saturated, because when i^* attaches to vP, it is the highest argument-introducing head, closing off the vP domain; once $-st$ attaches to vP, it is the highest argument-introducing head, closing off the vP domain; once $-st$ takes that position, there are no more arguments to saturate that θ -role. When $-st$ merges in the “figure” position, which is SpecpP according to Svenonius (2003, 2007), this is not the case. Merging i^* with a PP only closes off the PP domain, but there are more positions in the dominating vP in which an argument can be introduced. Therefore, the “figure” role can be introduced semantically as the external argument of the PP, but saturated by a DP introduced higher in the structure. This is schematically illustrated in the tree in (22), whose compositional semantics is given in (a)-(j). (See Wood 2015:21--27 for details about the semantic combinators assumed in this derivation.)

(22)

a. $\llbracket PP \rrbracket = \lambda s. \text{through}(\text{the crowd}, s)$

b. $\llbracket i^*_2 \rrbracket \leftrightarrow \lambda x \lambda s. \text{FIGURE}(x, s)$

- c. $\llbracket p^*P_{[S:D]} \rrbracket = \lambda x \lambda s. \text{FIGURE}(x,s) \ \& \ \text{through}(\text{the crowd},s)$
(c) comes from (a) and (b) by Event Identification
- d. $\llbracket -st \rrbracket = \lambda x. x$

 \approx 'The set of squeezing events, for which Bjartur is the agent, and which cause Bjartur to go through the crowd.'

In plain language, what happens in the interpretation of the tree in (22) is this. The lower i^*_2 head introduces a figure role. (We use the subscripts for presentational purposes only.) Since *-st* merges in the argument position made available by i^* , however, that role is not saturated within the p^*P . Semantic composition proceeds, leaving that role unsaturated, until the higher i^*_1 introduces an agent role. It combines in such a way that the two unsaturated roles are identified with one another, so that whatever merges as the external argument will be the semantic argument of both the agent relation and the figure relation. This is how a reflexive-like interpretation is achieved without any anaphoric element in the structure.

We are now in a position to compare the structural properties of voice, which we have proposed is i^* attaching to vP , and Svenonius's (2003, 2007) little p , which we have proposed is i^* attaching to a pP . Both voice and p introduce an external argument DP related to their

In fact, there are important distinctions between figure reflexives and *way*-constructions. For example, it would be possible (though perhaps marked) to form a *way*-construction from a verb like ‘murder’, as shown in (25a) and its English translation, but it is not possible to form a figure reflexive with ‘murder’, as shown in (25b) and its English translation. (Icelandic data comes from Einar Freyr Sigurðsson, p.c.)

(25) a. (?) Hann myrti sér leið til valda.

he murdered REFL.DAT way to power

‘He murdered his way to power.’

b. * Hann myrtist til valda.

he murdered-ST to power

INTENDED: *‘He murdered to power.’

The crucial difference is that *way*-constructions require activity verbs (or verbs coerced into an activity meaning); their meaning is constructed by adding a small clause to this activity verb interpretation. The semantics of figure reflexive constructions combines an activity with a semantically unsaturated path predicate, which forces the verb to be interpreted as a verb of motion. (Note that figure reflexives have no direct object that can be used to ‘measure out’ an activity event.) That is, in order for (25b) to be acceptable, it would have to be possible to interpret ‘murder’ as a verb of motion. In (25a), ‘murder’ is interpreted as an activity that creates the path expressed in the small clause, but it is not part of the traversal of the path.

To summarize this section, we have proposed that there is one head, *i**, that introduces the external arguments of vPs and pPs. Its syntactic properties are derived from its structural environment: it projects the syntactic category of its complement, it assigns the thematic role

implied by its complement, it can be expletive, and the range of interpretations available to it are constrained only by “Full Interpretation”.

4. Possessor Raising in Change-of-State vPs

In this section, we extend the system discussed in the previous two sections to Japanese adversity causatives. In order to do this, we first show how our system generates several other kinds of thematic dependencies, including clausal possession, change-of-state vPs, and possessor raising constructions, which, when combined, will derive the properties of Japanese adversity causatives.

4.1 Clausal possession, low and high

Myler (2014) demonstrates that clausal possession in Quechua can take several different forms. The form relevant to the present discussion is what Myler calls the “BE-APPL” construction in Cochabamba Quechua. It is exemplified in (26).

(26) Noqa-qta auto tiya-pu-wa-n.

I-GEN car be_{EXIST}-APPL-1O-3S

‘I have a car.’

(Myler 2014:306)

Myler argues that in (26), the possession relation is introduced internal to the possessed DP, but is saturated semantically by a DP introduced syntactically in the specifier of an appl head. Abstracting away from some details (Myler’s PredP in particular), the basic structure Myler proposes for (26) is as in (27).

(27) [_{AppIP} SPEAKER *appl* [_{VP} v_{EXIST} [_{DP} D [_{PossP} *poss* [_{NP} car]]]]]

Semantically, Poss introduces a possession relation, which remains unsaturated within its DP, much as the figure of figure reflexives remains unsaturated within the pP. The existential copula is argued to be semantically expletive, as is the appl head that ultimately introduces the possessor DP.

Importing this analysis into the current proposal, we can ask what kinds of heads Myler's *appl* and *poss* are. As for *poss*, it is quite possible that it is simply another use of bare *i**. Semantically, the possession relation would be the interpretation of *i** when it takes an nP complement.⁶ As for Myler's *appl*, it is fairly clear that this is also an unmodified *i**; it is interpreted expletively (and thus adds no thematic content to the structure on its own), so it falls into the class of heads like voice, low *appl* and little *p* (rather than canonical high *appl* or big *P*). Given the structure that Myler proposes, with *appl* taking a vP complement, the most immediately natural interpretation is that it is a kind of voice head. However, given that the existential copula makes no direct semantic contribution, it is also possible that *appl* (= *i**) merges below *v*, and is thus more like a low *appl* head. We will adopt the latter option for expository purposes, and propose the modified structure of (27) in (28).

$$(28) \quad [_{\text{VP}} \text{v}_{\text{EXIST}} [_{\text{DP}} \text{SPEAKER } i^* [_{\text{DP}} \text{D } [_{\text{nP}} i^* [_{\text{nP}} \text{car}]]]]]]$$

Even if (28) is the correct analysis of the Quechua BE-APPL construction, the other interpretation of (27) in the current proposal is nevertheless attested. Myler proposes that English sentences like *John has a car* have the structure in (29a), which according to our proposal would be (29b).⁷

$$(29) \quad \text{a. } [_{\text{voiceP}} \text{John voice } [_{\text{VP}} \text{v } [_{\text{DP}} \text{D } [_{\text{possP}} \text{poss } [_{\text{nP}} \text{car}]]]]]]$$

$$\text{b. } [_{\text{v*P}} \text{John } i^* [_{\text{VP}} \text{v } [_{\text{DP}} \text{D } [_{\text{nP}} i^* [_{\text{nP}} \text{car}]]]]]]$$

Recall that earlier, we argued that prepositions can either merge with a DP and then a vP (yielding what looks like a standard vP-adjunct pP) or with a vP and then a DP (yielding what looks like a standard high *appl*), with no difference in the thematic semantics entailed. If Myler's

⁶ We abstract away from how the D-feature of *i** is ultimately checked in this configuration. See Myler 2014 and Wood 2015 for some options. A possibility in addition to the ones discussed there is that the fact that the D head merges anyway, to form the DP, is enough to check the D-feature introduced.

⁷ For an extended defense of this structure, and arguments against preposition-incorporation approaches to the relation between HAVE and BE, see Myler 2014 chapters 2 and 4.

proposal is correct, we have another example of structures where the same syntactic elements can merge in a different order and yield the same semantic results. Clausal possession is built when a DP introduces a possession relation that is not saturated DP-internally. The elements needed to do so are a verbalizing v head and an (or rather, *the*) argument-introducing head, i^* . Either i^* merges first (introducing the possessor), followed by the little v head, or else the verbalizing v head merges first, followed by i^* (introducing the possessor). We will see below that these same analytical options present themselves in the distinction between possessor raising and adversity causatives. First, however, we must turn to an analysis of change-of-state vPs.

4.2 Change-of-state vPs

Marantz (2009a,b,2013) has argued that the basic structure of a change-of-state vP involves only one v head, which takes a DP complement as its argument. The way that change-of-state semantics are computed from this configuration is as follows. First, there is a general coercion rule such that the internal argument of a change-of-state is interpreted as a result state. This is illustrated in (30).

$$(30) \quad \llbracket \text{DP} \rrbracket \rightarrow \text{STATE}(\llbracket \text{DP} \rrbracket) = (\lambda x \lambda s. \text{state}(s, x))(\llbracket \text{DP} \rrbracket)$$

For both a causative sentence like *John shattered the window*, and an inchoative sentence like *The window shattered*, the interpretation of the DP internal argument would ultimately be as in (31).

$$(31) \quad \lambda s. \text{state}(s, ix.\text{window}(x))$$

What happens next depends on the structure. In an inchoative structure, with no external argument, the interpretation of v will introduce inchoative semantics of the sort often abbreviated as BECOME.

(32) $\llbracket v \rrbracket \leftrightarrow \lambda P_{\langle s,t \rangle} \lambda e \exists s. \text{BECOME}(s,e) \ \& \ P(s) / \text{---}$ (no external argument)

That is, v denotes the event of the result state coming to hold. If, however, there is an external argument, the interpretation of v can introduce a causing event, as illustrated in (33). (We will see again in section 4.4, as we saw earlier in section 4.1, that there are also instances where there is an external argument but v is interpreted as an expletive.)

(33) $\llbracket v \rrbracket \leftrightarrow \lambda P_{\langle s,t \rangle} \lambda e \exists e'. P(e') \ \& \ \text{CAUSE}(e',e) / \text{---}$ (external argument)

What is syntactically represented in a causative, then, is the causing event, introduced by v , and the result state, introduced by the coercion rule in (30) applied to the DP object. What is not syntactically represented is the “become” part of the change of state event. The change of state is syntactically represented in the juxtaposition of v and the DP object. That is, the v presents an event variable and the causing event and the DP creates the stative “event,” with the “change” meaning coming in as the interpretation of the relation between the events. What is available for adverbial modification (“John opened the door quickly”) and presupposition via *re-* prefixation (“John re-opened the door” presupposes “the door was open before”) are the “ e' CAUSES e , [change of] state s ” and the “state s ” from (32) and (33) — two things and no more. The change of state is not separately available. Note that this analysis of the relationship between (lexical) causatives and inchoatives built on the same root explicitly denies that either is built from the

other structurally or derivationally; the main event in the inchoative, asserted via v , is “become,” while “become” finds no explicit syntactic representation in the causative.

We can notate this analysis of the source of change of state semantics within causatives as a semantic combinatory rule in the notational style of Heim & Kratzer (1998) as in (34).

(34) If α is a branching node, and $\{v, DP\}$ the set of α 's daughters, then

$$\llbracket \alpha \rrbracket = \llbracket v \rrbracket ((\lambda P_{\langle s,t \rangle} \lambda e \exists s. \text{BECOME}(s,e) \ \& \ P(s))(\llbracket DP \rrbracket)).$$

That is, $v+DP$ is interpreted by taking the interpretation of the DP (result state), applying it to the “become” predicate, and feeding that to the interpretation of v . Since the “become” predicate cannot be tied to any specific syntactic node, but results instead from a special combinatory rule, it cannot be modified by adverbs like *quickly* or *again*, singled out for presupposition by *re-*prefixation, or targeted for clausal negation. Note that this rule must be understood to apply only to the eventive v that coerces the change of state interpretation of the DP complement, and not to the stative v involved in deriving clausal possession. As Myler (2014) argues, the latter is pronounced as *have* in English, while the former is pronounced as *get* (see Wood & E.F. Sigurðsson 2014). Since the difference in pronunciation correlates with a difference in interpretation, the distinction between stative and eventive v must be rooted somewhere in the syntax, but we will not develop an account of what that difference is here (see Alexiadou et al. 2015 for the same conclusion).

4.3 Possessor raising

Possessor raising constructions such as (35) seem to combine properties of the analyses in the previous two subsections.

(35) Ha-yalda kilkela le-Dan et ha-radio.

the-girl spoiled to-Dan ACC the-radio

‘The girl broke Dan’s radio on him.’ (Pykkänen 2008:46, citing Landau 1999)

On the one hand, they involve an external possessor in what looks like a low applicative position saturating a possessor relation determined DP-internally. (See Pykkänen 2008 on the low applicative analysis.) On the other hand, they involve change-of-state semantics on the internal argument. Given the analyses in the previous two subsections, the syntax creates two kinds of interpretive demands on the structure. In order for the possessor relation to be saturated by the external DP, the possessor relation must remain unsaturated. And yet, in order for the change-of-state semantics to be computed, the DP has to be interpreted as a result state. This is illustrated schematically in (36).

Notice, however, that this result can be achieved by combining the analysis of change-of-state vPs with the analysis of figure reflexives. For change-of-state semantics, we have a coercion rule as in (37).

(37) $[[DP]] \rightarrow STATE([DP]) = (\lambda x \lambda s. state(s, x))([DP])$

Given the denotation of a DP with an unsaturated possessor relation, we have composition as in

(38), where (38b) derives from (38a) by function composition.

(38) a. $(\lambda x \lambda s. \text{state}(s, x)) (\lambda y. \text{ix.POSS}(x, y))$

b. $\lambda y \lambda s. \text{state}(s, \text{ix.POSS}(x, y))$

Given the denotation in (38b), low appl will be interpreted as expletive, and the argument it introduces will saturate the possession relation. All the other semantic processes outlined in the previous subsection can apply in exactly the same way.

Note that possessor raising constructions of this sort tend to have, in addition to the purely thematic possessive reading, a kind of “affectedness” reading. The translation of (35), for example, is not just ‘The girl broke Dan’s radio,’ but ‘The girl broke Dan’s radio *on him*.’ We do not have much to say about this affectedness reading, which is also found in the Japanese adversity causatives to be discussed in the next subsection (see the translation in (40ii)), except to note that such affected roles are strictly speaking distinct from the tier of thematic interpretive roles such as beneficiary, possessor, agent, etc. Bosse et al. (2012) argue that this kind of meaning is projected on a non-truth-conditional semantic tier, which operates in parallel to, but is strictly distinct from, the truth-conditional tier (see also Horn 2013). In particular, unlike arguments including standard applicative arguments, these affected arguments stand outside the scope of negation. Here, we focus on the aspects of meaning that are projected on the truth-conditional tier and provide no new account of the source of affected readings (see Bosse et al. for further discussion).

4.4 Japanese adversity causatives

Japanese adversity causatives are formally similar to Icelandic figure reflexives in that the interpretation of an external argument depends on the properties of the internal argument. In particular, a thematic “possessor” role is introduced inside the DP complement of *v*, and saturated by a DP in SpecvoiceP.

- (39) $[_{\text{voiceP}} \text{Taroo } \textit{voice} [_{\text{VP}} \textit{die-CAUSE} [_{\text{DP}} \text{POSSESSOR son}]]]$
- 

An adversity causative is illustrated in (40), along with the bracketing to indicate its syntactic structure.

- (40) $[_{\text{voiceP}} \text{Taroo-ga} [_{\text{VP}} [_{\text{DP}} \text{musuko-o}] \text{sin-ase}]]\text{-ta.}$
 $[_{\text{voiceP}} \text{Taroo-NOM} [_{\text{VP}} [_{\text{DP}} \text{son-ACC}] \text{die-CAUS}]]\text{-PAST}$

(i) ‘Taro caused his son to die.’

(ii) ‘Taro’s son died on him.’

Japanese adversity causatives have a few notable properties (Oehrle & Nishio 1981; Miyagawa 1989; Pytkänen 2008). First, they seem to look, morphosyntactically, like plain transitive lexical causatives, and as indicated in the first translation of (40), they may be interpreted as such. Second, the adversity reading is only possible when the “affectee” subject is understood as the possessor of the internal argument. Third, adversity causatives are generally only possible on transitive structures for which there also exists an intransitive, unaccusative counterpart. Consistent with this last generalization, adversity causatives are morphophonologically identical to lexical causatives, built directly on a verbal root, and not to syntactic causatives in the many cases where these are morphophonologically distinguishable (e.g., in particular when the syntactic causative is built on top of a lexical causative).

The analysis of the adversity causatives that we propose builds on an analysis of possessor raising outlined in the previous subsection, combined with the analysis of clausal possession of the English sort outlined in section 4.1. Recall that there, we saw that clausal possession can be derived in at least two ways from a DP with an unsaturated possessor relation. First, i^* and the possessor can combine with the DP possessee first, with the result then combining with little v . This was our adaptation of Myler’s proposal for Quechua BE-APPL constructions. Second, little v can combine with the DP possessee first, followed by i^* and the possessor; this was the analysis of English clausal possession with *have*.

The analysis of possessor raising given in the previous subsection was essentially the first option, combined with a change-of-state predicate. The analysis of Japanese adversity causatives is essentially the second option, combined with a change-of-state predicate. Adversity causatives look like plain transitive causatives because they have the same syntactic structure as plain transitive causatives, shown in (41).

$$(41) \quad [_{vP} \text{ EXT-ARG } i^* [_{vP} v \text{ DP }]]$$

Recall that earlier, we argued that the interpretation of i^* in the context of a vP depends on the semantics of that vP . For a change-of-state event that can happen without an agent, i^* may be interpreted as expletive. We also noted, however, that when there is an external argument present, i^* cannot be interpreted as expletive unless there is some other way to integrate the external argument into the semantics of the vP . If the internal argument DP introduces a possessor role which remains unsaturated within that DP, the external argument can be integrated into the semantics of the vP by saturating that possessor role. This is illustrated in (42).

$$(42) \quad \text{a. } \llbracket \text{DP} \rrbracket = \lambda y \lambda s. \text{state}(s, ix.POSS(x, y) \ \& \ \text{son}(x))$$

$$\text{b. } \llbracket v \rrbracket \leftrightarrow \lambda x. x$$

$$c. \llbracket vP \rrbracket = \llbracket v \rrbracket ((\lambda P_{\langle s,t \rangle} \lambda e \exists s. BECOME(s,e) \& P(s))(\llbracket DP \rrbracket)).$$

(by combinatory rule in (32))

$$\rightarrow \llbracket v \rrbracket (\lambda y \lambda e \exists s. BECOME(s,e) \& state(s,ix.POSS(x,y) \& son(x)))$$

(by Function Composition)

$$\rightarrow \lambda y \lambda e \exists s. BECOME(s,e) \& state(s,ix.POSS(x,y) \& son(x))$$

(by Functional Application)

$$d. \llbracket i^* \rrbracket \leftrightarrow \lambda x. x$$

$$e. \llbracket v^*P \rrbracket = \lambda e \exists s. BECOME(s,e) \& state(s,ix.POSS(x,Taroo) \& son(x))$$

\approx ‘The set of events of Taroo’s son coming to be in state s ’⁸

Consider how this analysis captures the properties of adversity causatives mentioned at the beginning of this section. First, they look, morphosyntactically, like plain transitive causatives, because they have the same syntactic structure as plain transitive causatives. In particular, the allomorph of little v chosen in a transitive environment for a particular root will be the same in the plain lexical causative and in the adversity causative. Second, the adversity reading is only available when the subject is the possessor because it is the possessor role that allows the subject to be integrated into the semantics of the vP in the first place. Without the possessor role, i^* would have to introduce some other role (such as agent) in order for the DP external argument to be integrated into the semantic interpretation. Third, adversity causatives are only possible on transitive structures for which there also exists an unaccusative counterpart

⁸ Note that the root of the verb will typically name the end state, which in a sentence like (40) will be the state of being dead; we omit this conjunct from the derivation in (42).

because it is precisely those structures that allow for the expletive alloeme of *i** in the context of a vP.

Note that according to this analysis, the causative morpheme in the Japanese adversity causative does not indicate causative semantics. The affix that we generally call the causative morpheme is simply the way that little *v* is pronounced when there is a syntactic external argument. In many cases, the presence of an external argument correlates with a causative interpretation of little *v*. In the Japanese adversity causative, however, there is no assertion of a causing event. Thus, when a sentence like (40) is negated, as in (43), only three out of four imaginable interpretations are actually available. (Thanks to Yohei Oseki for discussion of the Japanese facts and judgments of the data.)

(43) Taro-ga musuko-o sin-ase-nakat-ta.

Taro-NOM son-ACC die-CAUS-NEG-PAST

- | | |
|---|-------------------------------------|
| (i) a. ‘Taro’s son died, but Taro didn’t kill him.’ | <i>(negation of causing event)</i> |
| b. ‘Taro’s son didn’t die at all.’ | <i>(negation of result)</i> |
| (ii) a. *‘Taro’s son died, but without any cause.’ | <i>(*negation of causing event)</i> |
| b. ‘Taro’s son didn’t die at all.’ | <i>(negation of result)</i> |

In the ordinary causative interpretation, given in (43i), clausal negation can negate either the causing event or the result. That is, the ordinary causative interpretation under negation is compatible with the son dying, but not by the asserted cause. In the adversity causative interpretation, on the other hand, only the result can be negated, although the adversity implication remains. (Taro’s son dying would have resulted in adversity for Taro.) It is not possible in the presence of negation to negate a cause of the change of state while retaining the assertion of the change of state (and the adversity implication: nothing caused his son to die on

Taro, although he did). These facts support our claim that causative semantics are not present in the adversity causative, despite the presence of causative morphology. The “causative” morphology does not reflect semantics, but rather the presence of little *v* in a particular syntactic structure.

The present analysis of the Japanese adversity causative agrees with that in Pylkkänen (2008) in denying that the construction is built on the semantics of the inchoative form of the base verb and in providing an essentially transitive syntactic structure to the construction. The strongest evidence contrasting the inchoative (e.g., “Taro’s son died”) with the change of state semantics within the adversity causative is the impossibility of modifying the change of state with adverbials that can occur with the inchoative (e.g., “from natural causes,” or “by itself”). Our analysis disagrees with Pylkkänen’s in three crucial respects. First, as explained above, the present analysis denies that the adversity causative asserts causative semantics; some evidence for this conclusion is the failure of negation to deny causation, which is possible for negation with the lexical causative. Second, Pylkkänen analyzes the affected argument as an applicative argument; however, according to the distinctions motivated in Bosse et al. (2012), the affected role is not that of an applicative argument, being unable to scope under negation. Finally, Pylkkänen (2008) builds the adversity causative on top of the adversity passive, which she analyzes as an applicative construction; however, the adversity passive is a “high” construction, which can embed a syntactic causative, while the adversity causative is a “low” construction, necessarily built on the verbal root – the causative thus could not be built on top of the passive.

What distinguishes between Japanese and English, preventing English from having the “adversity” causative reading of transitive verb phrases, is (i) the availability of the possessor raising structure, which allows a possessor role introduced inside a DP to be saturated externally

to that DP in non-stative contexts, and (ii) the possibility for active voice above little *v* not to assign the “agent” role, if another role is available. In fact, English does have adversity causatives when it can, exceptionally, do possessor raising, as in sentences like *John broke an arm*, which can mean that John is the adversely affected (inalienable) possessor of the arm that broke. Like in Japanese, *John didn’t break an arm*, under the adversity causative reading, entails that John’s arm was not broken, whereas *John didn’t break the window* is perfectly compatible with the window breaking in some other way.

5. Conclusion

In this chapter, we have proposed an understanding of the syntax and semantics of external arguments that depends on an autonomous syntax, where the atoms of representations do not carry inherent semantic values. We first proposed a restricted system of argument introduction, where a single argument-introducing head varies only in terms of the syntactic context it is merged in. The relevant syntactic factors for eventual semantic interpretation include the category of its complement along with whether or not a lexical root adjoins to it. Semantically, this argument introducing head generally assigns to the second constituent it merges with the θ -role implied by the first constituent it merges with. After introducing the properties of the argument introducing head, we applied the resulting system to a set of cases where the interpretation of an external argument depends on a θ -role introduced somewhere lower in the structure. Icelandic figure reflexives involve an external argument that bears a figure role introduced inside a lower pP; clausal possession involves an external or applied argument bearing a possessor role introduced inside a lower DP; and adversity causatives and possessor raising involve, essentially, the analysis of clausal possession superimposed over change of state vP semantics. The basic system ends up being both restrictive and flexible. The restrictiveness

stems from the fact that all argument introducing heads reduce to one syntactic head; any and all syntactic, morphological, and interpretive differences between *prima facie* distinct heads must be reduced to properties of the structure they occur in. We retain a tight connection between syntactic structure and thematic interpretation, because the latter is derived by interpretive rules defined on the former. And yet, the system is flexible, in that there is no particular principle forcing a DP with a particular thematic interpretation to occur in a particular syntactic position. All that is required is that semantic composition leads to a well-formed semantic representation.
