

Pair-list readings of questions: new evidence from specificational pseudoclefts*

Jing Ji

McGill University

1. Introduction

Universal quantifiers in questions such as (1) lead to three interpretations that can be recognized in their congruent answers. The individual reading of (1) asks for answers like (1a). The functional reading expects answers like (1b). The pair-list reading, interpreted as ‘For every guest *x*, which dish did *x* make?’, requires a pair-list answer like (1c).

- (1) Which dish did every guest make? (Krifka 2001)
- a. (Every guest made) pasta.
 - b. (Every guest made) his favorite dish.
 - c. Al (made) the pasta; Bill, the salad; and Carl, the soup.

Compared to the other two readings, the pair-list reading is more constrained regarding syntactic configurations. First, pair-list readings exhibit subject-object asymmetry. When the quantified NP occupies the object position, such as (2), pair-list readings disappear.

- (2) Which dish upset every guest?
- a. Pasta.
 - b. #His favorite dish.
 - c. #The pasta (upset) Al; the salad, Bill; and the soup, Carl.

Second, there is an asymmetry between universal and non-universal quantifiers. Non-universal quantifiers like ‘most guests’ in the matrix clause do not allow pair-list readings, as in (3).

- (3) Which dish did most guests make? (Krifka 2001)

*I thank Bernhard Schwarz for his detailed comments and advice in every step of this project. I also thank Michael Wagner for helpful discussions, the McGill syntax-semantics reading group, and the abstract reviewers and the audiences of NELS 52 and TOM 13.

- a. Pasta.
- b. Their favorite dish.
- c. #Al the pasta, and Bill the salad.

There has been a debate on the pair-list interpretation of questions with universals. One approach is quantification into question acts (Krifka 2001), where the universal quantifier scopes over a covert question-embedding predicate QUEST. Take the pair-list reading of the question in (1) as an illustration (repeated in (4a)). A sketch of the analysis is in (4b).

- (4) a. What did every guest make? – Al, the pasta; Bill, the salad; and Carl, the soup.
 b. [every guest] λy [QUEST[what did y make]]

This paper presents a new argument that quantification into speech acts, if available at all, cannot be the only path to pair-list readings of questions with universals. The argument builds on new data from specificational pseudoclefts (SPCs). We (i) show that SPCs behave like question-answer pairs (QAPs) in allowing pair-list readings with universals in the subject position; and (ii) argue that the approach of quantifying into speech acts is incompatible with pair-list SPCs compared with alternative approaches. Since pair-list questions and SPCs are subject to similar constraints, the analysis of pair-list in SPCs could carry over to questions, indicating that the wh-quantifier interaction does not necessarily involve a speech act layer in the grammar.

The rest of the paper is organized as follows. Section 2 reviews two prominent approaches to composing pair-list questions, i.e., the function-based approach (Engdahl 1985, Chierchia 1993, Xiang 2021) and quantifying into speech acts (Karttunen 1977, Krifka 2001). Section 3 presents novel data from SPCs showing that SPCs can take a pair-list shape and pair-list SPCs and QAPs are subject to parallel constraints. Section 4 implements pair-list SPCs with quantifying into speech acts in two conceivable ways. Both suffer from overgeneration. Section 5 demonstrates that alternative approaches without reference to speech acts capture properties of pair-list SPCs naturally. Section 6 concludes.

2. Two prominent approaches to composing pair-list questions

There have been rich literature on composing pair-list questions with quantifiers. This section reviews two prominent approaches, each motivated by one of the two properties of pair-list readings, respectively.

2.1 The function-based approach

The function-based approach, originated in Engdahl (1985) and developed in Chierchia (1993) and Xiang (2021), regards pair-list questions as a special case of functional questions analyzed as involving quantification over a function, e.g., (5). The answer can either specify a function by giving its intension, such as *his favorite dish*, or specify a function by giving its extension (viz., a pair-list answer), e.g., $\{\langle \text{Al, pasta} \rangle, \langle \text{Bill, salad} \rangle, \langle \text{Carl, soup} \rangle\}$.

- (5) Which dish did every guest make?
 $\lambda p \exists f [\text{range}(f) = \text{dish} \wedge p = \wedge \forall y [\text{guest}(y) \rightarrow \text{made}(f(y))(y)]]$
'Which f (a function to dishes) is s.t. every guest y made $f(y)$?'

This approach is motivated by the subject-object asymmetry uniformly observed in functional and pair-list readings of questions with universals. A minimal pair is shown below.

- (6) Which woman did every guest like? ($\checkmark$ Individual, $\checkmark$ Functional, $\checkmark$ Pair-list)
a. Anna.
b. His mother.
c. Al likes Mary; Bill likes Sue; Carl likes Jill.
- (7) Which woman likes every guest? ($\checkmark$ Individual, $\times$ Functional, $\times$ Pair-list)
a. Anna.
b. #His mother.
c. #Mary likes Al; Sue likes Bill; Jill likes Carl.

Assuming functionality, the absence of pair-list interpretation of (7) can be explained since its logical form (shown in (8)) leads to a Weak Crossover violation. According to Chierchia (1993), the *wh*-trace carries two indices, a functional index i bound by the *wh*-phrase and an argument index j co-indexed with the quantifier. To bind the j -index carried by the *wh*-trace, the quantifier has to move from the object position, which inevitably crosses over a co-indexed expression (the *wh*-trace).

- (8) Which woman likes every guest?
*[which-woman _{i} ...[every-guest _{j} ...[t_i^j likes t_j]]]

2.2 Quantifying into speech acts

The second approach, proposed by Karttunen (1977) and updated by Krifka (2001), argues that pair-list interpretation involves quantification into speech acts. This approach is motivated by the asymmetry between universals and non-universals ((1) vs. (3)) and their relation to the algebra of speech acts. Krifka claims that the algebra of speech acts is more limited than a Boolean algebra, containing only conjunction, but not disjunction. For instance, (9) can be interpreted as a conjunction of two assertions while (10) can only be interpreted as a disjunction of two propositions rather than a disjunction of two assertions.

- (9) Al made the pasta, and Bill made the salad.
a. 'I assert: Al made the pasta, and Bill made the salad.'
b. 'I assert: Al made the pasta, and I assert: Bill made the salad.'
- (10) Al made the pasta, or Bill made the salad.

- a. ‘I assert: Al made the pasta, or Bill made the salad.’
- b. #‘I assert: Al made the pasta, or I assert: Bill made the salad.’

The asymmetry between universals and non-universals can be explained by assuming that only universals can scope over speech acts as they are generalized conjunctions, e.g., (11a). Non-universals cannot be reduced to conjunction but require both conjunction and disjunction, e.g., (11b).

- (11) a. Every guest came. $\Leftrightarrow$ Al came **and** Bill came **and** Carl came.
- b. Most guest came. $\Leftrightarrow$ Al came and Bill came, **or** Bill came and Carl came, **or** Carl came and Al came.

To implement speech act quantifiers, Krifka assumes a new type *a* for speech acts. An illocutionary operator combines with a sentence radical meaning to form a speech act. For example, a question operator (QUEST) is a function from a question (a set of propositions) to a question act, whereas ASSERT is a function from a proposition to an assertion. Assuming ‘&A’ as the conjunction of all speech acts in a set of speech acts **A**, a pair-list question denotes a conjunction of question acts like (12), while a pair-list answer denotes a conjunction of assertions, such as (13).

- (12) $\llbracket \text{what did every guest make} \rrbracket$
 $= \llbracket [\text{every guest}]_{\langle ea, a \rangle} \lambda y [\text{QUEST}_{\langle stt, a \rangle} [\text{what did y make}]] \rrbracket$
 $= \&\{\text{QUEST}(\lambda p \exists x [\text{dish}(x) \wedge p = \hat{\text{made}}(x)(y)]) : \text{guest}(y)\}$
- (13) $\llbracket \text{Al made the pasta, Bill made the salad, and Carl made the cake} \rrbracket$
 $= \&\{\text{ASSERT}(\hat{\text{made}}(\text{the pasta})(\text{Al})), \text{ASSERT}(\hat{\text{made}}(\text{the salad})(\text{Bill})),$
 $\text{ASSERT}(\hat{\text{made}}(\text{the cake})(\text{Carl}))\}$

3. Pair-list SPCs

This paper poses a challenge to the approach of quantifying into speech acts. The evidence comes from specificational pseudoclefts (SPCs). This section likens the analysis of SPCs to that of question-answer pairs (QAPs), and section 4 demonstrates that quantifying into speech acts cannot be adjusted to analyze pair-list SPCs.

3.1 Parallels between pair-list SPCs and QAPs

In Heycock (1994)’s terminology, pseudocleft sentences consist of a wh-clause, a simple form of the copula (*is/was*), and a ‘counterweight’. (14) features a postcopular constituent that functions as the predicate of ‘what John likes’. In (15), the postcopular phrase is not the predicate of the wh-constituent; instead, it specifies a property of the subject of the wh-clause, thus known as specificational pseudoclefts.

- (14) What John likes is important.

- (15) What John likes is himself.

Ross (1972) reported that the counterweight of SPCs can be clausal. To this, we add the novel observation that clausal counterweights can take pair-list shape, as in (16a) and (16b), although pair-list counterweights are somewhat marginal when they repeat the verb in the *wh*-clause, as in (16b).

- (16) a. What every guest did was Al made the pasta, Bill made the salad, and Carl made the soup.
b. ?What every guest made was Al made the pasta, Bill made the salad, and Carl made the soup.

Moreover, constraints on pair-list readings of questions and SPCs match in two aspects, suggesting that they are the same phenomenon. First, we observe subject-object asymmetry for both QAPs and SPCs. Pair-list readings disappear when a universal quantifier occupies the object position instead of the subject position.

- (17) a. What did every guest make? – Al, the pasta; Bill, the salad; and Carl, the soup.
b. ?What every guest made was Al made the pasta, Bill made the salad, and Carl made the soup.
- (18) a. What upset every guest? – # The pasta, Al; the salad, Bill; and the soup, Carl.
b. *What upset every guest was the pasta upset Al, the salad upset Bill, and the soup upset Carl.

Second, similar to QAPs, there is an asymmetry between universal and non-universal quantifiers w.r.t. pair-list interpretation of SPCs. The SPC with universals in (19b) allows a pair-list counterweight, whereas the SPC with non-universals in (20b) does not.

- (19) a. What did every guest make? – Al, the pasta; Bill, the salad; and Carl, the soup.
b. ?What every guest made was Al made the pasta, Bill made the salad, and Carl made the soup.
- (20) a. What did most guests make? – # Al, the pasta; Bill, the salad.
b. *What most guests made was Al made the pasta, and Bill made the salad.

3.2 Likening SPCs to QAPs

The existing approach to SPCs likens SPCs with clausal counterweights to QAPs. den Dikken et al. (2000) and Schlenker (2003) propose that the *wh*-clause of SPCs denotes a question and the counterweight denotes its answer. Their proposal is based on the syntactic and semantic similarities between SPCs and QAPs. Syntactically, the *wh*-clause of SPCs

behaves like a wh-question rather than a free relative (FR). As is shown in (21), while FRs freely allow the addition of *-ever*, the wh-clause of SPCs does not. Also, SPCs differ from FRs in allowing topicalization, as shown in (22).

- (21) a. What(ever) John does is interesting. (FR)
 b. I wonder what(*ever) John does. (wh-question)
 c. what(*ever) John does is write novels. (SPC).
- (22) a. *[to Mary, what he gave] caused a scandal. (FR)
 b. ?to Mary, what will he give? (wh-question)
 c. ?[to Mary, what he will never give] is any wine. (SPC).

Semantically, similar to QAPs, where the universal quantifier in the answers cannot take scope over the indefinite in the wh-question, the wide-scope reading for the universal quantifier in the counterweights of SPCs is unavailable.

- (23) a. Every article that appeared bothered a friend of mine. ($\exists\forall/\forall\exists$)
 b. What bothered a friend of mine was [every article that appeared]. ($\exists\forall/*\forall\exists$)
 c. What bothered a friend of yours? – A: [Every article that appeared (bothered a friend of mine)]. ($\exists\forall/*\forall\exists$)

The parallels between SPCs and QAPs regarding pair-list readings discussed in section 3.1 further strengthened this proposal of likening SPCs to QAPs. At the same time, SPCs can inform the debate as to how such pair-list readings arise, as we will now see.

4. Quantifying into speech acts is incompatible with pair-list SPCs

This section implements pair-list SPCs with quantifying into speech acts. We consider two conceivable analyses employing QUEST, differing in the analysis of the copula and concomitant analyses of wh-clause and counterweight. Both are shown to overgenerate if universals are permitted to scope over QUEST.

4.1 Assuming a vacuous copula

Krifka (2001) assumes that in conversational games, speech acts are transitions between states. For instance, an initiating question act Q can move from a neutral state *s* to a state *s'*, where a corresponding answer act A is expected and will lead back to a neutral state *s''*, shown in (24).

- (24) $A(Q(s)) = A(s') = s''$,
 where Q is appropriate for state *s*, and A is appropriate for state *s'*

Given this, an SPC can be taken as a composition of question and answer acts by assuming a semantically vacuous copula.

The problem with this analysis is the overgeneration of indirect answers. den Dikken et al. (2000) points out that while a *wh*-question allows an indirect answer, such as (25b), SPCs generally realize only direct question-answer relations. A contrast is shown in (26).

- (25) What did John buy?
a. He bought some wine. (direct answer)
b. He didn't buy any wine. (indirect answer)
- (26) a. ?What John bought was he bought some wine. (direct answer)
b. *What John bought was he didn't buy any wine. (indirect answer)

One might suggest that the contrast comes from the fact that QAPs require double interlocutors while SPCs only involve a single interlocutor. We show that this is not the case since self-answering questions also allow indirect answers. Assume the context in (27). It is felicitous for Alice to respond to her own question with an indirect answer below.

- (27) *Context: Alice and Bob are best friends. Alice heard that Bob invited a guest to his birthday party. Alice asked herself:*
Who did he invite? He didn't even invite his best friend.

Therefore, we need a way to exclude indirect answers in the grammar. But assuming a vacuous copula does not allow us to select semantic answers.

4.2 Assuming an equating copula

Another way of implementing pair-list SPCs with quantifying into speech acts is to assume an equating copula. Schlenker (2003) proposes that the copula of an SPC means identity, equating the pre-copular question and the post-copular answer. Analyzing SPCs with this assumption requires coercing speech acts to propositions. Since each question act corresponds to a unique question, we can apply a type-shifting operator TA to a question act, yielding a proposition that is the most informative true answer to the question. Similarly, we assume a type-shifter (T) mapping an assertion to the proposition asserted.

$$(28) \quad TA_{\langle a, st \rangle}(QUEST(Q)) = \iota p[p \text{ is the most informative true answer to } Q]$$

$$(29) \quad T_{\langle a, st \rangle}(ASSERT(A)) = A$$

Thus the truth-conditional meaning of an SPC is derived by equating two propositions. For example, the SPC in (30a) is true only if the conjunction of propositions coerced from each question is equivalent to the conjunction of propositions coerced from each assertion, shown in (30c).

- (30) a. ?What every guest made was Al made the pasta, Bill made the salad, and Carl made the soup.
 b. $\llbracket \text{every guest} \rrbracket = \lambda P_{\langle e, st \rangle} \cdot \bigwedge_{x \in G} P(x)$, where $G = \{\text{Al, Bill, Carl}\}$
 c. $\llbracket (30a) \rrbracket = 1$ iff $\llbracket \llbracket \text{every guest} \rrbracket \lambda y [\text{TA}[\text{QUEST}[\text{which dish } y \text{ made}]]] \rrbracket$
 $= \bigwedge \{T(\text{ASSERT}(\hat{\text{made}}(\text{Al}, \text{the pasta}))), T(\text{ASSERT}(\hat{\text{made}}(\text{Bill}, \text{the salad}))), T(\text{ASSERT}(\hat{\text{made}}(\text{Carl}, \text{the soup})))\}$

The consequence of the type-shifting is that non-universal quantifiers like *most guests* can scope over QUEST in virtue of composing with the output of TA because speech acts are coerced to propositions that are of a Boolean type, for which both conjunction and disjunction are defined. This type-shifting exactly corresponds to Krifka (2001)'s analysis of embedded questions under extensional verbs, like *know*, since questions embedded by *know* appear to have pair-list readings, and the non-universal quantifier appears to take a wide scope, as in (31).

- (31) a. Doris knows what most guests made. (Krifka, 2001)
 'She knows that Al made the pasta and Bill made the salad.'
 b. $\llbracket \text{most guests} \rrbracket = \lambda P_{\langle e, st \rangle} \cdot \bigvee_{Y \subseteq G \wedge |Y| > 1/2|G|} [\bigwedge_{x \in Y} P(x)]$, where $G = \{\text{Al, Bill, Carl}\}$
 c. $\llbracket \text{what most guests made} \rrbracket$
 $= \llbracket \llbracket \text{most guest} \rrbracket_{\langle est, st \rangle} \lambda y [\text{TA}[\text{QUEST}_{\langle stt, a \rangle}[\text{what } y \text{ made}]]] \rrbracket$

However, this analysis overgenerates in SPCs because sentences like (32) are incorrectly predicted to be acceptable with the logical form of the wh-clause in (31c).

- (32) *What most guests made was Al made the pasta and Bill made the salad (or Al made the pasta and Carl made the cake, or Bill made the salad and Carl made the cake).

To avoid this issue, Krifka might maintain that there is no landing site above TA. Quantifiers can only scope between TA and QUEST, as in (33). In this case, TA applies to a conjunction of question acts in a point-wise way, as in (34). Nevertheless, the problem remains since the pair-list reading of questions with non-universals embedded by *know* cannot be derived, indicating that there must be a path to pair-list readings other than quantifying into speech acts.

- (33) TA [every guest λy [QUEST [what y made]]]

- (34) a. $\text{TA}(\text{QUEST}(Q)) = \iota p [p \text{ is the most informative true answer to } Q]$
 b. $\text{TA}(\&\Theta_{\langle a, t \rangle}) = \bigwedge \{ \text{TA}(\alpha) \mid \alpha \in \Theta \}$

Further evidence from diagnostics of speech acts confirms our claim as speech acts are regarded as the necessary condition for matrix clause syntax and the use of root modal particles by Krifka (2014), but both matrix clause syntax and root modal particles are absent from SPCs. On the one hand, McCloskey (2006) points out that *wonder*, *ask*, and certain

other question-embedding verbs allow for main clause syntax, at least in some varieties of English, especially Irish English, such as (35). But SPCs and embedded questions under verbs like *know*, *find out* do not allow main clause syntax, e.g., (36) and (37).

- (35) The baritone was asked what did he think of Mrs. Kearney's conduct.
- (36) *People found out what did the baritone think of Mrs. Kearney's conduct.
- (37) *What did John buy was he bought some wine.

On the other, in German, verbs like *wonder*, *ask* allow for root modal particles like *denn*, e.g., (38). But SPCs and verbs like *know* do not allow *denn*, e.g. (39) and (40). Therefore, if the pair-list readings of questions under *know* and SPCs come from quantifying into speech acts, Krifka needs to explain the behavior of *denn* and the absence of main clause syntax, which requires extra stipulations.

- (38) John fragt sich, wen Maria (denn) getrogen hat.
'John wonders whom Maria PART met'
- (39) John weiß, wen Maria (*denn) getrogen hat.
'John knows whom Maria PART met'
- (40) Was Maria (*denn) sucht ist ihr Regenschirm.
'What Maria PART seeks is her umbrella'

5. Alternative approaches are compatible with pair-list SPCs

This section demonstrates that compared to quantifying into speech acts, approaches without reference to speech acts can capture the two properties of pair-list readings of SPCs naturally, such as the family-of-questions approach by Fox (2012), the function-based approach by Engdahl (1985), Chierchia (1993), Xiang (2021), and incremental quantification by Bumford (2015). Here we demonstrate one possibility with local quantification and binding into a functional trace.

As described in section 2.1, the function-based approach takes pair-list readings of questions with universals as quantification over functions, and a pair-list answer specifies functional relations by giving its extension. To illustrate, the precopular *wh*-clause and the counterweight of the SPC in (41a) have the denotation in (41b) and (41c), respectively.

- (41) a. ?What every guest made was Al made the pasta, Bill made the salad, and Carl made the soup.
- b. $[[\textit{what every guest made}]]$
 $= \lambda p. \exists f [\text{range}(f) = \text{dish} \wedge p = \wedge \forall y [\text{guest}(y) \rightarrow \text{made}(f(y))(y)]]$
- c. $[[\textit{Al made the pasta, Bill made the salad, and Carl made the cake}]]$
 $= \wedge \forall y [\text{guest}(y) \rightarrow \text{made}(f_0(y))(y)]$

To implement SPCs with the function-based approach, we assume an equating copula and an Answerhood operator *Ans* Dayal (2016) at LF. Since *Ans* maps a question to its most informative true answer, the copula can equate two propositions without type mismatch. For example, the SPC in (41a) has the denotation in (42), which is true iff the proposition denoted by the counterweight is the maximally informative true answer to the question denoted by the wh-clause.

$$(42) \quad \llbracket (41a) \rrbracket = [\lambda p. \lambda q. p = q](\llbracket (41c) \rrbracket)(\llbracket Ans \rrbracket^w(\llbracket (41b) \rrbracket)) = 1 \text{ iff} \\ \llbracket (41c) \rrbracket \text{ is the most informative true answer to } \llbracket (41b) \rrbracket$$

We show that the function-based approach captures the two properties of pair-list SPCs naturally. First, the subject-object asymmetry is a consequence of Weak Crossover by assuming functionality, as demonstrated in section 2.1. Second, the asymmetry between universals and non-universals follows from Dayal's Answerhood operator if we assume every question combines with *Ans* and that *Ans* triggers the presupposition that the question's Hamblin set contains a true member that entails any other true member. As an illustration, assume there are three players A, B, C, and three numbers 1, 2, 3 such that A picked 1, B picked 2, and C picked 3 in w_0 . The Hamblin set of the wh-clause in (43a) and (43b) are shown in (44) and (45), respectively. The underlined propositions are true in w_0 . While the Hamblin set of the wh-clause with universals has a unique true answer in w_0 , the Hamblin set of the wh-clause with non-universals does not contain a proposition (represented as a disjunction of conjunctions) that entails all the other true answers in any given possible world. Hence, (43b) is ruled out by violating the uniqueness presupposition triggered by *Ans*.

- (43) a. ?What every player picked was A picked 1, B picked 2, and C picked 3.
b. *What most players picked was A picked 1 and B picked 2, or A picked 1 and C picked 3, or B picked 2 and C picked 3.

$$(44) \quad \llbracket \text{what every guest picked} \rrbracket = \\ \{ \lambda w. \text{pick}_w(A,1) \wedge \text{pick}_w(B,2) \wedge \text{pick}_w(C,3), \\ \lambda w. \text{pick}_w(A,1) \wedge \text{pick}_w(B,2) \wedge \text{pick}_w(C,1), \\ \lambda w. \text{pick}_w(A,2) \wedge \text{pick}_w(B,2) \wedge \text{pick}_w(C,3), \\ \lambda w. \text{pick}_w(A,3) \wedge \text{pick}_w(B,1) \wedge \text{pick}_w(C,2), \dots \}$$

$$(45) \quad \llbracket \text{what most guests picked} \rrbracket = \\ \{ \lambda w. (\text{pick}_w(A,1) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(C,3) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(A,1) \wedge \text{pick}_w(C,3)), \\ \lambda w. (\text{pick}_w(A,1) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(C,1) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(A,1) \wedge \text{pick}_w(C,1)), \\ \lambda w. (\text{pick}_w(A,2) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(C,3) \wedge \text{pick}_w(B,2)) \vee (\text{pick}_w(A,2) \wedge \text{pick}_w(C,3)), \\ \lambda w. (\text{pick}_w(A,3) \wedge \text{pick}_w(B,1)) \vee (\text{pick}_w(C,2) \wedge \text{pick}_w(B,1)) \vee (\text{pick}_w(A,3) \wedge \text{pick}_w(C,2)), \\ \dots \}$$

There are alternative ways to derive the asymmetry between universals and non-universals of pair-list SPCs with the function-based approach, such as restricting the function domain to a unique minimal witness set (Groenendijk and Stokhof 1984).

6. Conclusion

This paper poses a challenge to the approach of quantifying into speech acts with new evidence from SPCs. We show that SPCs with clausal counterweight can take pair-list shape, and pair-list SPCs should be analyzed as QAPs. We argue that the approach of quantifying into speech acts, which allows universals to scope over questions, cannot be adjusted to analyze pair-list SPCs, whereas alternative accounts capture properties of pair-list SPCs naturally. The similar constraints held in both pair-list questions and SPCs suggest that quantification into speech acts, if available at all, cannot be the only path to pair-list readings of questions.
