

Clitic placement and the anti-verb-second effect in European Portuguese: insights from uninflected verbs*

Michelle Sheehan, Newcastle University

Abstract

Clitic placement with European Portuguese *uninflected* verbs is problematic for prosodic analyses. While ‘proclisis triggers’ give rise to obligatory proclisis with *inflected* verbs, they often lead to *optional* proclisis/enclisis with *uninflected* verbs (Raposo & Uriagereka 2008), except for aspectual/quantificational adverbials with head-like behaviour (Martins 2013a). These patterns provide support for a syntactic ‘Anti-V2 requirement’, whereby clitics usually raise to adjoin to T and *either*: (a) an XP raises to/through spec FinP and the verb stays in Asp (resulting in proclisis); *or* (b) the verb raises through T to Fin (resulting in enclisis); but not both (building on Fernández-Rubiera 2009, 2010). The special behaviour of uninflected infinitives can be explained by the possibility of clitics attaching to a lower verbal host and then moving with that host to T resulting in enclisis (Raposo and Uriagereka 2008). Aspectual/quantificational heads block verb movement to T, ruling out enclisis via ‘low fusion’.

Keywords: enclisis; proclisis; mesoclis; finiteness; infinitive; clitics; verb second; V2, second position; Tobler-Mussafia

1 Clitic placement in European Portuguese with inflected verbs

Many pages have been dedicated to the description and analysis of European Portuguese (EP) (and Western Ibero-Romance) clitic placement. With very few exceptions, these analyses have focused on the patterns observed with finite inflected verbs. These clitic placement patterns are complex, difficult to acquire, and subject to (some degree of) variation across speakers (which I will abstract away from here). Before turning to non-finite uninflected

* I acknowledge funding from the *British Academy/Leverhulme Small Research Grant* on ‘Argument expression in UK Heritage Portuguese’ (PI: Michelle Sheehan, Co-I: Ioanna Sitaridou) and *Agence Nationale de la Recherche - German Research Foundation (ANR-DFG)* project ‘Uncovering verb-second effects. An interface-based typology’ (PIs: Maia Duguine, CNRS-IKER & Georg A. Kaiser, Konstanz). Thanks also to the audiences at the *Workshop on constraints on linearization*, DfG, Bochum, Germany, March 2024 and *V2, or not V2, that is the question: On verb placement in interrogatives*, Bayonne, France, March 2023 for feedback, especially Maia Duguine and Ana Maria Martins. Finally, thank you to two anonymous reviewers whose comments led to significant improvements in the ideas presented here.

verbs, I first summarise the patterns with finite inflected verbs, drawing on the ample literature on this topic (see Barbosa 1996, 2000, Madeira 1992, 1995, Martins 1994, 2000, 2013a, Duarte & Matos 2000, Raposo and Uriagereka 2008, Fernandez-Rubiera 2009, 2010, Costa, Fiéis & Lobo 2015, Luís and Kaiser 2016).¹

Clitics can appear either in: proclisis (preceding the verb), enclisis (following the verb) or mesocclisis (between the verb and a future/conditional inflectional morpheme):²

- (1) a. ...*que te =telefono* (proclisis)
 ...that 2SG=telephone.PRES.1SG
 ‘...that I telephone you.’
- b. *telefono =te* (enclisis)
 telephone=2SG
 ‘I telephone you.’
- c. *telefonar =te =ei* (mesocclisis)
 telephone =2SG =FUT.1SG
 ‘I will telephone you.’

Descriptively, we can speak of proclisis ‘triggers’, with enclisis/mesocclisis being the default pattern which results where no such trigger is present. This is the case even though some accounts take enclisis to be basic (Duarte & Matos 2000), whereas others take the opposite view (Madeira 1992, 1995, Martins 1994, 2000, Costa, Fiéis & Lobo 2015). On our account, neither proclisis nor enclisis is basic as both involve movement to the phase edge, but there is a sense in which enclisis arises as a last resort where proclisis fails to obtain.

¹ Very similar patterns can be found in other Western Ibero-Romance languages (e.g. Galician and Asturian). For a comparative view of these varieties in finite contexts, see Fernández-Rubiera (2009, 2010). I will limit myself to a discussion of EP here as the patterns are complex enough in this language alone.

² I follow the Leipzig glossing rules and hence use = throughout to indicate clitic dependencies. This is not without its issues as it requires me to make assumptions about the relevant dependencies not always present in the writing conventions of the language. Nonetheless, I believe it is a clearer way to present Portuguese examples to those who may not be familiar with the language. Thanks to a reviewer for asking me to justify this choice.

1.1 Proclisis triggers

Proclisis triggers can be divided into (A) phrases and (B) heads (see Martins 2013a for an extensive description with examples):

- (A) Phrasal triggers: wh-phrases (2a), negative phrases (2b), quantifier phrases (QPs) (2c), contrastive foci (2d).

- (2) a. **Como** *te= posso ajudar?*

how you= can.1SG help

‘How can I help you?’

- b. **Nada** *te= posso dar.*

nothing you= can.1SG give

‘Nothing can I give you.’

- c. **Alguém** *te= pode ajudar.*

someone you= can.3SG help

‘Someone can help you.’

- d. **PARA A RUA** *se= escapou o Gaspar (não foi para o jardim)*

onto the road self= escaped.3SG the Gaspar neg was into the garden

‘ONTO THE ROAD Gaspar escaped.’ (Martins 2013a: 2266)

While both enclisis and proclisis are possible with some QPs (*muitos X* ‘many X’, *bastantes X* ‘quite a few X’, *raros X* ‘a few X’, *qualquer X* ‘some X’, *alguns X* ‘some X’, *tamanho X* ‘such an X’, *cada X* ‘each X’) resulting in interpretational differences (see Martins 2013a: 2248-2254), for the most part, the patterns with strongly non-referential quantifiers (e.g., *alguém* ‘someone’ *algo*, *algum X*, *todo*, *tudo*), are clear and not subject to variation.

Crucially, all XPs that trigger proclisis only do so where they occur in a preverbal position, as discussed below.

- (B) Head triggers can be divided into three separate classes: (i) overt complementisers (C-heads) (*que*, *se*) (3a); (ii) Negation (Neg-heads) (3b); (iii) Certain light aspectual/quantificational adverbs (Asp/Q-heads) (3c):

- (3) a. *Acho* **que** *te= vejo.*

think.PRES.1SG that 2SG= see.1SG

‘I think I (can) see you.’

b. *Não te= vejo.*

neg 2SG= see.1SG

‘I can’t see you.’

c. *Já te= disse.*

already 2SG= said.1SG

‘I’ve already told you.’

While the triggers in (2) are clearly phrasal and the triggers in (3a-b) are fairly clearly heads, the status of adverbial triggers, as in (3c), is more complex, as discussed in the next Section.

1.2 Adverbial proclisis triggers can be heads

Some adverbial proclisis triggers are phrases and others are heads and independent diagnostics are needed to distinguish between the two. Consider the following non-exhaustive list of adverbial proclisis triggers, based on the description in Martins (2013a: 2254-2259):

(4) Adverbial proclisis triggers

Focalising adverbs: *também* ‘also’, *até*, *mesmo* ‘even’, *só*, *somente*, *apenas* ‘only’, *logo* ‘actually, later, immediately’, *talvez* ‘possibly’, *quase* ‘almost’

Emphatic adverbs: *sempre* ‘after.all/indeed’, *bem* ‘really’, *lá* ‘there’

Aspectual adverbs: *já* ‘already’, *ainda* ‘still’

Negative adverbs: *raramente* ‘rarely’, *nunca* ‘never’, *mal* ‘hardly’

In addition to this list, Martins (2013a) also notes that fronted contrastively focused adverbs also trigger proclisis of the kind seen in (2d). Focalising adverbs often form a constituent with a DP which they scope over. Such examples are clearly parallel to example (2c), involving a fronted QP:

(5) a. [*Mesmo o papagaio*] *me= pareceu triste*

even the parrot 1SG= seemed.3SG sad

‘Even the parrot looked sad to me.’

b. [*Apenas o Jorge*] *se= mostrou inconformado*

only the Jorge self= showed.3SG non-conformist

‘Only Jorge proved to be non-conformist.’

c. [*Também o Pedro*] *te= traiu*

also the Pedro 2SG= betrayed.3SG

‘Pedro also betrayed you.’ (Martins 2013a: 2255)

However, a subset of adverbial proclisis triggers behave like heads rather than phrases when they surface alone. For example, like inflected verbs, some adverbial proclisis triggers can function as the answers to yes-no questions (Martins 1994, 2013b, Castro & Costa 2003, Santos 2009).

(6) Q: *Ele já encontrou a chave?*

he already found.3SG the key

‘Has he already found the key?’

A: *Já/ encontrou/ sim/ é/ foi*

already/ found.3SG / yes is/ was

‘Yes.’ (Santos 2009: 59)

In example (6), as indicated, there are several ways to offer an affirmative response to a question containing the proclisis trigger *já* in European Portuguese, with repetition of this adverb in isolation being very natural. The same is true with the adverbs *ainda* ‘still’, *também* ‘also’ and *só* ‘only’. Without going into details, Martins (1994, 2013b) has argued that such examples involve head-movement of a finite verb or adverb to the polarity-related head Σ , followed by ellipsis. In order for the adverbs in question to undergo this movement and in the process block verb-movement, they would, presumably, need to be heads.

A second special behaviour of these adverbial heads is that they can modify possessors, which have themselves been argued to be heads (Castro & Costa 2003: 109, citing Britto 2001:569):

(7) a. *a ainda minha mulher*

the still my woman

‘still my woman’

b. *a já sua noiva*

the already his fiancée

‘already his fiancée’

Castro and Costa (2003) argue that EP prenominal possessors are heads, hence the fact that they cannot be postposed to receive focus (unlike Italian possessors, which, they claim, are phrases):

- (8) a. **O livro meu/MEU*
 the book my
 b. *O MEU livro*
 the my book
 ‘MY book’ (Castro and Costa 2003: 109)

As they show, only head-like quantifiers can modify EP prenominal possessors and this follows, they claim, if what is at stake is head-to-head adjunction rather than phrasal modification. This pattern also holds of *também* ‘also’ but not *só* ‘only’, possibly because *só* permits association with focused constituents which it does not directly merge with, meaning that it can naturally occur dislocated from a head it modifies:

- (9) *Só o MEU livro*
 only the my book
 ‘Only MY book’

Again, this special behaviour suggests that these EP adverbs are actually heads.

Further evidence that (some of) these adverbs are heads comes from the fact that they (rather than the verb) get reduplicated in instances of emphatic affirmation (in answer to a negative tag question) (Martins 1994: 14):

- (10)a. *O João ainda não saiu, pois não?* [Context]
 the João still NEG left POIS NEG
 ‘João hasn’t left yet, has he?’
 b. *Saiu, saiu.*
 left left
 c. *Já saiu, já.*
 already left already

‘Yes, he HAS.’

d. **Já* *saiu*, *saiu*.

already left left

e. **Já* *saiu*, *já* *saiu*

already left already left

As shown in (10b), emphatic affirmation is usually conveyed by repetition of the finite verb in EP. However, where an adverbial head like *já* ‘already’ is present (10c-e), it is the adverb rather than the verb (or the adverb+verb) which must be repeated.

Again, Martins (1994, 2007, 2013b) provides an analysis of emphatic affirmation based on the idea that there is a dedicated projection ΣP located just below CP. As already noted, this projection houses negation and is also targeted by adverbial heads like *já*. Abstracting away from the precise analysis of this phenomenon as it would need modifications to be compatible with our current proposal (but see Martins 1994, 2007), what is important for our purposes is that: (i) this again suggests that some adverbial proclisis triggers in EP enter the derivation as heads and not phrases, as they again pattern with finite verbs; and (ii) these adverbial heads raise to the projection otherwise occupied by negation, just below C. This pattern also holds for *só* ‘only’, *ainda* ‘still’ and *também* ‘also’. In general, while not all the head-like adverbial proclisis triggers pattern alike with respect to all of these diagnostics (for the independent reasons mentioned), the following adverbials pass multiple such tests, suggesting that they are indeed heads:

(11) Adverbial heads triggering proclisis:

- i. *já* ‘already’,
- ii. *ainda* ‘still’,
- iii. *também* ‘also’,
- iv. *só* ‘only’

It is important to be clear, however, that not all of the adverbial proclisis triggers in (4) behave like heads (even where they surface alone). As Martins (1994) shows, *sempre* ‘indeed/always’ cannot, for example, be reduplicated in instances of emphatic affirmation (12c):

(12) a. *O João nem sempre apoiou a Maria, pois não?* [Context]

the João not.even always supported the Maria POIS NEG

‘João hasn’t always supported Maria, has he?’

b. *Sempre* apoiou a Maria, *apoiou*.

indeed supports the Maria supported

‘Of course he always HAS.’

c. **Sempre* apoiou a Maria, *sempre*.

indeed supported the Maria indeed

Despite this, *sempre* ‘indeed/always’ is a proclisis trigger, but we must conclude that it is a phrasal trigger. Non-head adverbial proclisis triggers fall under A, as XPs functioning variously as wh-phrases, negative phrases, quantifier phrases (QPs) or contrastive foci.

1.3 Enclisis (and mesocclisis)

Thus far, we have only discussed proclisis. Descriptively, enclisis is the elsewhere pattern found in contexts lacking a proclisis trigger, including with preverbal subjects/topics (Barbosa 1996, 2000, Madeira 1992, Raposo and Uriagereka 2008, Martins 2013a):

(13)a. *Eu disse- =te*.

I said.1SG=you

‘I told you.’

b. *Tivesse =me o Pedro ajudado,*

had.3SG.IMPF.SUBJ =me the Pedro helped

‘If Pedro had helped me...’

c. *Se o Pedro me= tivesse ajudado, ...*

If the Pedro me= had.3SG.IMPF.SUBJ helped

‘If Pedro had helped me ...’ (Madeira 1992: 103)

Example (13a) shows that enclisis obtains in matrix clauses with a preverbal subject and (13b) shows that enclisis is also the default in embedded clauses not introduced by a complementiser (in contrast with (13c)). Duarte & Matos (2000) and Costa, Fiéis & Lobo (2015) note a tendency for children and adults (in informal speech) to extend the use of

enclisis to contexts in which we would expect proclisis. This implies that enclisis is the unmarked order, whereas proclisis is triggered in specific contexts (and may be lost).³

Where the verb is in the future or conditional, and no proclisis trigger is present, the result is mesoclis, as the future/conditional suffixes follow the clitic. This pattern is reported to be limited to more formal registers and is sometimes replaced with enclisis by younger speakers (Duarte & Matos 2000):

- (14) *A Maria {ver=te-á. / *te= ver-á / %ver-á =te} amanhã.*
 the Maria see=2SG-FUT / 2sg=see-FUT / see-FUT =2SG tomorrow
 ‘Maria will see you tomorrow.’

More generally, the future and conditional are often replaced, in spoken language, by the present/periphrastic future or the imperfect respectively, resulting in enclisis (in the case of the periphrastic future, on either the infinitive or the auxiliary, if clitic climbing takes place) rather than mesoclis:

- (15) a. *A Maria {vai =te ver/ vai ver=te} amanhã.*
 the Maria goes =2SG see goes see=2SG tomorrow
 ‘Maria will see you tomorrow.’
 b. *Eu dava =lhe uma prenda.*
 I gave.IMP=3SG.DAT a present
 ‘I used to give/would give her a present’

There is therefore a sense in which mesoclis is a subtype of enclisis which targets a verb stem, rather than an inflected verb. For the remainder of this article, I will focus mainly on the enclisis vs. proclisis contrast. It will be argued that mesoclis arises in a particular ‘enclisis’ context where T is realised as a future/conditional affix (see Section 2.2).

³ As already noted, I will not have space to consider how to model this variation, here.

2 Towards an analysis of EP clitic placement

2.1 Previous analyses

As noted above, there has been substantial previous work on patterns of clitic placement with finite verbs in EP. Analyses can roughly be divided into: (i) prosodic accounts, (ii) mixed syntactic/prosodic accounts and (iii) syntactic approaches. Prosodic accounts either attribute the placement of EP clitics to a prosodic restriction on clitics, banning them from being initial in the intonational phrase (Barbosa 2000) or, conversely, propose that proclisis is triggered by the presence of a preceding heavy functional word in the same prosodic domain (Duarte & Matos 2000). On such approaches, clitic placement is not tied to syntactic verb movement. While such accounts have their attractions, as we shall see below, it is not obvious how they can account for the very different behaviour of uninflected verbs in EP or for the minimally different behaviour of different proclisis triggers with these uninflected verbs.

Mixed prosodic/syntactic accounts tend to rely on the notion that clitics need a phonological host but propose that syntactic movement can be triggered in contexts where this condition is not met. For example, in the approach of Raposo and Uriagereka (2008), the head to which the clitic adjoins is itself a clitic and, if it has no other potential local host, it must attract the verb in the syntax as a last resort (so-called ‘verb swallowing’), resulting in enclisis.

On syntactic accounts, the placement of EP clitics is not governed by prosody and rather results from independent syntactic properties of the language. Verb movement plays a crucial role in all such accounts (to my knowledge). The verbal complex has been variously proposed to (a) move past the clitic to the Σ position below C (Martins 1994), (b) adjoin to the clitic in C (Madeira 1992) or (c) pick up the clitic on its way to the C head Fin (Fernández-Rubiera 2009, 2010). I will adopt an approach of the final kind, developing Fernández-Rubiera’s (2009, 2010) proposal because it offers a parsimonious account of EP clitic placement and, as I will show below, with some modifications, can accommodate the special behavior of non-finite verbs and even the specific patterns observed with a subset of proclisis triggers in this context.

As we shall see shortly, EP clitic placement is sensitive to morphosyntax in three important respects:

- I. Uninflected verbs pattern differently from inflected verbs.

- II. With uninflected verbs, clitic placement is sensitive to the presence of tense in a given domain.
- III. With uninflected verbs, clitic placement is affected by the base-generated syntactic position and head/specifier of the proclisis trigger.

If prosody is not directly sensitive to inflection, tense and syntactic (as opposed to linear) position within a prosodic phrase, this suggests that clitic placement must be a syntactic matter.⁴

2.2 *The Anti-V2 analysis*

Fernández-Rubiera (2009, 2010) proposes that Fin has what I will call an ‘anti-V2 property’ in EP. That is to say that Fin has a single edge feature requiring movement of *either* a head (to Fin) *or* an XP to/through spec FinP, but never both. I will essentially adopt Fernández-Rubiera’s proposal, but my implementation will be somewhat different from his. Fernández-Rubiera (2009, 2010) proposes that clitics are base generated as heads in a dedicated projection in the clausal spine. This kind of approach faces challenges as we shall see below, so I adopt the alternative view that clitics are base generated in argument positions and move to a higher syntactic position (following Kayne 1991, Madeira 1992, 1995, Barbosa 2000, Martins 2000, Raposo and Uriagereka 2008). I assume that EP clitics bear a [uT] feature, and this means that they must get to T (one way or another) during the course of the derivation (see also Kayne 1991, Martins 1994, 2000, Barbosa 2000). Following an insight from Chomsky (1995), I assume that the defining property of clitics is that they are both heads and phrases so that their initial movement is not subject to the head-movement constraint. In simple finite clauses, I propose that clitics raise and adjoin to T, immediately satisfying their [uT] feature.⁵

⁴ There have been interesting proposals which highlight the alignment between prosodic and syntactic domains but there is also widespread agreement that the two do not always align. In the cases discussed below, the presence or absence of a phasal boundary has no obvious prosodic effect, but there are syntactic effects which can be independently diagnosed, as discussed.

⁵ A reviewer asks why object clitics bear a [uT] feature upon entering the derivation in EP. I do not have a deep rationale for this except to say that I am assuming that uninterpretable features in Minimalist theory are merely a way of modelling grammatical dependencies. The observation (argued for at length here) is that, in EP, clitics seek a dependency with T, and the [uT] feature is a way of modelling this. This is presumably a grammatical property with no deep explanation, as it is an uninterpretable feature - assuming that at least some aspects of

Enclisis arises where the verb, which ordinarily lands in Asp, must move to Fin in order to satisfy the latter's edge feature (Fernández-Rubiera 2009, 2010). As the verb moves through T (because of the Head Movement Constraint – Travis 1984), it adjoins to the cl+T complex resulting in enclisis (or mesoclisism if T is realised as a conditional/future suffix). To accommodate multiple clitics, we must assume that multiple adjunction to T is possible:

- (16)a. [_{FinP} [[V+v+Asp]+ **[clitic+T]**]+Fin [_{TP} [_{AspP}...]]]
 b. [*vemos*] + [*o* + T] > *vemo=lo* 'We see him.'
 c. [*dei*] + [*lhe* + o + T] > *dei=lho* 'I gave her it.'
 d. [*cantar*] + [*o* + *ia*] > *cantá=lo=ia* 'I would sing it.'

This derivation applies in contexts where no proclisis trigger is present but also where a potential trigger is present but remains in a position lower than the verb. In such cases, the verb will be the preferred means to satisfy Fin's edge feature, resulting in enclisis:⁶

- (17) *Vejo =te pouco*
 see.1SG =2SG little
 'I don't see you much.'

In (17), the QP *pouco* 'little' remains in a postverbal position and so the verb raises to Fin. If *pouco* had raised to spec FinP, this would have resulted in proclisis, with the verb remaining in Asp, below the clitic+T. Note that, on this approach, rather than verb-movement being a last resort, strictly speaking, there is a certain 'optionality' involved. XP proclisis triggers (wh-phrases, QPs and contrastive foci) have the option of remaining in situ (with interpretational effects) and where they do, the result is enclisis as the verb then raises to Fin to satisfy the edge condition:

- (18)a. *Disseste =lhe o quê?*
 said.2SG =him.DAT the what

syntax operate independently of semantics. This is clearly unconnected to Case, as object clitics have dative/accusative case assigned by a head lower than T.

⁶ This is effectively a version of Raposo & Uriagereka's (2008) verb-swallowing except that it is motivated by a syntactic edge condition (the Anti-V2 requirement) rather than a prosodic constraint.

- ‘What did you tell him?’
- b. *O que lhe= disseste?*
 the what him.DAT= said.2SG
- (19)a. *O Gaspar escapou=se PARA A RUA!*
 the Gaspar escaped =self for the road
 ‘Gaspar escaped into the street.’
- b. *PARA A RUA se= escapou o Gaspar*
 for the street self=escaped.3SG the Gaspar (Martins 2013a: 2266)

EP permits *wh*-in situ as well as *wh*-movement in constituent questions and, as shown in (18a-b), proclisis is only triggered in instances of *wh*-movement. Likewise, EP permits contrastive foci to either raise to the C-domain or to remain in situ. Again, proclisis is triggered only where overt movement takes place (19a-b). I will not discuss the differences in meaning between the (a) and (b) examples in (18)-(19) here. As an anonymous reviewer points out, verb movement is not really ‘optional’ here in the true sense of the word, as we might assume that XP movement to/through spec FinP is feature driven, whereas head-movement to Fin is not. There is a sense, therefore, in which head movement is still a last resort on this approach.

On this analysis, proclisis results where verb movement does *not* take place (as is the case for Fernández-Rubiera 2009, 2010, but also similarly to Martins 2000, Raposo and Uriagereka 2008, Rouveret 1992 w.r.t. $\Sigma/F/W$). On our approach, the verb fails to raise through T and intervening heads to Fin wherever one of the following two things happen instead:

- (a) An XP moves to/through spec FinP;⁷
 (b) a complementiser/negative/adverbial head moves to Fin.⁸

In such cases, the clitic remains in T and the verb raises only to Asp. Note that this means EP clitics are phonological clitics requiring an adjacent verbal host at PF, but sometimes

⁷ A reviewer asks what prevents the clitic+T cluster from raising to Fin to satisfy the edge requirement (resulting in proclisis). My tentative answer to this excellent question is that clitics are not themselves heavy enough to satisfy Fin’s edge requirement. This issue requires further consideration, however, to avoid circularity.

⁸ This is different from Fernández-Rubiera’s (2009) approach also in that an adverbial head can also move to Fin, as we shall see shortly.

occurring in a different phrase to that head in the syntax (see also Madeira 1992, 1995, Martins 1994). Figures 1-2 illustrate, in simplified form, this minimally revised version of Fernández-Rubiera's (2009, 2010) proposal, the only difference being that clitics are base generated in thematic positions:

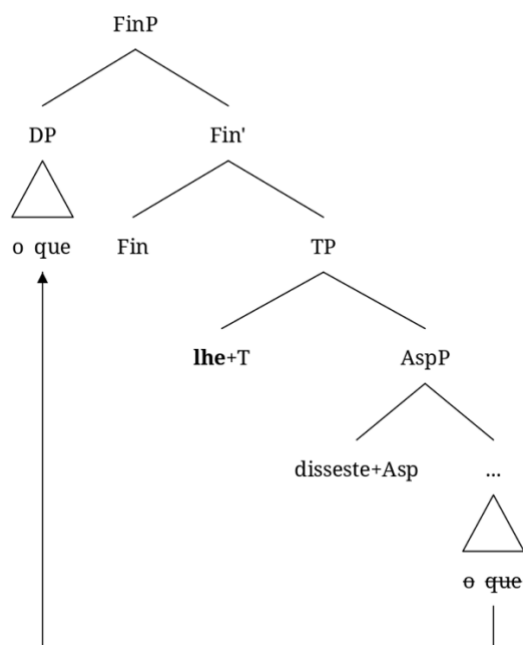

Fig 1: XP movement to spec FinP = proclisis

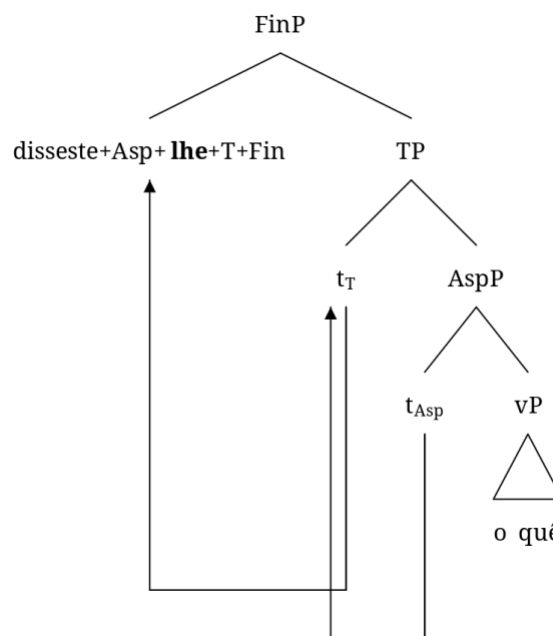

Fig 2: Verb movement to Fin = enclisis

This is the essence of the proposal; I flesh out some additional details in the following section. The main focus of this paper is the behaviour of uninflected verbs but before considering these more complex patterns, let us consider some details of the treatment of finite verbs.

2.3 *Fleshing out the analysis*

A crucial component of this analysis is that Spec FinP can only be targeted by QPs including negative quantifiers, whPs and contractive Foci and *not* by other XPs including topics and non-focused or QP subjects.⁹ This is necessary in order to capture the fact that when it comes to phrases, only strong quantifiers (including whPs, negative phrases and contrastive foci) trigger proclisis in EP. As with some other syntactic approaches, we are therefore forced to assume that these XPs all share some kind of operator/A-bar feature which forces them to

⁹ Recall that weak quantifiers such as *muito* 'many' *bastante* 'quite a few' etc. when fronted are compatible with both proclisis and enclisis. With subtle meaning differences. We must assume that, where these QPs trigger proclisis, they bear an operator/A-bar feature and so raise through spec FinP and where they don't they function as base-generated Topics, leading to enclisis/mesocclisis.

raise to/through spec FinP. Neutral subjects, like topics, must lack this feature and so are unable to satisfy Fin's edge feature.

A potentially attractive alternative would be to adopt the view that both topics and subjects are base generated too high to be potential satisfiers of Fin's edge feature. It is conceivable that in matrix clauses, preverbal topics are base-generated higher than Fin, and indeed some approaches to EP clitic placement assume this is also the case for all preverbal subjects (see Barbosa 1996, 2000 for details). If subjects never occupy spec TP, this would also explain why they cannot intervene between a fronted wh-phrase and the verb (which on our approach remains in Asp, rather than having moved to C):

- (20) **Quando {*a Maria} veio { a Maria}?*
 when the Maria came.3SG the Maria
 'When did Maria come?' (Barbosa 2000: 65)

However, as an anonymous reviewer notes, there are good reasons to reject the idea that all preverbal subjects in EP occupy a topic position above Fin (see Costa & Duarte 2002, Sheehan 2016). This is true not least because embedded questions are different from (20), as is well known (Barbosa 2000, citing Âmbar 1988):

- (21) *Não sei quando {a Maria} vem {a Maria}.*
 not know.1SG when the Maria comes the Maria
 'I don't know when Maria is coming.'

As (21) shows, a subject can actually intervene between a fronted wh-phrase and the finite verb in EP embedded clauses. Crucially, this embedded preverbal position is reserved for subjects; non-subject topics are not permitted (22), as Costa & Duarte (2002: 163) point out:

- (22) **Perguntei que livro, à Maria, lhe= deram.*
 asked.1SG what book to Maria 3SG.DAT= gave.3PL

It therefore seems that the most parsimonious analysis is to assume that subjects merely lack the relevant operator feature needed to satisfy Fin's edge feature (unless they are focused or relativised). This means that verb movement will be required even where a subject occupies spec TP, because (non-focused/relativised) subjects simply cannot be attracted to spec FinP

as they lack the relevant feature. Of course, this means that, in matrix clauses, preverbal subjects must occupy a topic position, as the verb, by hypothesis, occupies Fin. Postverbal subjects in matrix clauses could occupy either spec TP or a lower vP-internal position. This leaves us with no explanation for the unacceptability of (20), unfortunately, but it does capture the contrast in (21)-(22) as there is a preverbal subject position below Fin (spec TP), but not a Topic position.

To summarise so far, proclisis can arise in the following ways:

(23) Proclisis

- a. [_{FinP} **que/se**+Fin [_{CP} t_{que/se}[_{TP} **cl**+T [_{AspP} V+v+voice+Asp [_{VoiceP} t_{cl} t_{voice} [_{vP} ...]]]]]]]
- b. [_{FinP} **não**+Fin [_{ΣP} t_{não} [_{TP} **cl**+T [_{AspP} V+v+voice+Asp [_{VoiceP} t_{cl} t_{voice} [_{vP} ...]]]]]]]
- c. [_{FinP} **whP** Fin [_{TP} **cl**+T [_{AspP} V+v+voice+Asp [_{VoiceP} t_{cl} t_{voice} [_{vP} ...]]]]]]]

As illustrated, proclisis is triggered by internal merge of a head or phrase in the Fin domain. In (24a) a complementiser base generated in C moves to Fin via head-movement. In (24b), a negative head moves to Fin; whereas in (23c) a QP raises to spec FinP, possibly on the way to a higher position. Conversely, enclisis/mesocclisis results where the verb moves to Fin as a last resort, picking up the clitic on the way (plus any future/conditional suffixes). As noted above, this is an alternative means to satisfy Fin's edge condition and it is strictly incompatible with merge or move of something else in/to the Fin domain.

(24) Enclisis

- a. [_{FinP} [[V+v+voice+Asp]+[**cl**+T]]+Fin [_{TP} t_T [_{AspP} t_{Asp} [_{VoiceP} t_{voice} [_{vP} ... t_{cl}]]]]]]]

This is essentially Fernández-Rubiera's (2009, 2010) proposal but with two small differences: (i) complementisers are not base generated in Fin and (ii) the clitic originates in an argument position and raises to adjoin to T. The first small change is necessary in order to offer a coherent account of complementisers. If complementisers were instantiations of Fin, then we would expect them to have an edge position necessitating phrasal movement to spec FinP, contrary to fact.¹⁰ If they are themselves heads in a lower projection then we can maintain the idea that Fin always requires external merge of a head or specifier. The second

¹⁰ Thanks to Gereon Müller for raising this issue with me.

small change is more substantive. It will prove crucial in our account of cliticisation patterns with uninflected verbs.

A further substantive difference is that I claim that a small class of adverbial proclisis triggers (see Section 1.2) are also minimax categories, like clitics themselves, which qualify as both heads and phrases. I propose that these adverbials are base generated as minimax categories in Asp, but then raise to a head-position (just as clitics do). For this reason, these adverbs share with clitics the property of their first movement not being subject to Travis' (1984) Head Movement Constraint (following Chomsky 1995). In this way, these elements are attracted directly to Σ (skipping T), from where they may be required to undergo head movement (along with Σ) to Fin, as a last resort in the absence of any XP-movement to spec FinP:

$$(25) \quad [_{\text{FinP}} \textbf{já} + \Sigma + \text{Fin} \quad [_{\Sigma} t_{\textbf{já}} [_{\text{TP}} \textbf{cl} + \text{T} \quad [_{\text{AspP}} t_{\textbf{já}} [_{\text{VoiceP}} \textbf{V} + \textbf{v} + \text{Voice} \quad [_{\text{VP}} \dots]]]]]]]$$

Crucially, the base-generation of these adverbs in Asp and their status as both phrases and heads means that, in such contexts, the verb cannot raise to Asp or on to T (or higher). Rather, the verb must remain in Voice.

An anonymous reviewer asks what triggers Asp/Q movement to Σ and what allows verb movement to Asp not to happen in such contexts. My proposal is that as heads in the verbal extended projection, these adverbials are really particles or uninflected auxiliaries, which, as is the case with English modals, take over some main-verb properties in a clause, despite lacking the crucial property of inflection. For this to be the case, we just need to assume that Asp has a requirement to be filled in EP and that the Head Movement Constraint applies. It cannot be the case that EP inflected verbs have a $[\text{uAsp}]$ feature themselves or this feature would not be checked in the presence of an aspectual head. This means that this movement, like movement to Fin is triggered by the probe and not the goal. Movement of either the verb or Asp to Σ , on the other hand, appears to be a more general property of EP syntax (see Martins 1994, 2000). A separate issue is whether there is empirical support for the claim that finite verbs occupy a lower position (below Asp) in the presence of an adverbial proclisis trigger. The main evidence for this is that presented in Section 1.2.

A reviewer also asks me to clarify how we can derive the correct word order in clauses like the following, where a complementiser satisfies Fin's edge condition and both the subject and adverb precede a clitic in proclisis:

(26)a. *Acho que a Maria já te= conhece.*

believe.1SG that the Maria already 2SG= knows

‘I believe that Maria already knows you.’

b. *Acho que a Maria já não te= quer.*

believe.1SG that the Maria already NEG 2SG= loves

‘I think that Maria doesn’t love you anymore.’

In (26a), it must be that the C-head *que* has raised to Fin and the Asp head *já* has raised to Σ . This leaves the question of what position the subject occupies. The only possibility is that it must occupy spec Σ P. The alternative order whereby the subject follows *já* is perhaps not totally ruled out, but it is certainly much less natural. It seems to be a feature of EP, that whenever the polarity head Σ is active, the subject must raise to spec Σ P. The same would be true with clausal negation. A further question is how *já* comes to precede the clausal negator *não* in (26b). The most likely analysis is that *já não* is a constituent in such cases, located in Σ , either by base generation or after movement of *já* and right adjunction to negation. Note that the same pattern arises with *ainda* and *também* which both precede negation when co-occurring in the same clause.¹¹ This would follow if Asp bears a $[u\Sigma]$ feature in such contexts, forcing movement to Σ .

In sum, we depart again from Fernández-Rubiera’s (2009, 2010) proposal, because in our account:

- (i) The clitic originates in an argument position and raises to spec TP;
- (ii) Some Aspectual/focalizing adverbs are minimax categories which move to Fin (like negation), whereas other adverbs like *raramente* raise as XPs to spec FinP.

Fernández-Rubiera, on the other hand, claims all adverbial proclisis triggers raise as XPs to spec FinP. To summarise, then, in simplex finite clauses, my proposal is that proclisis is derived as follows:

(27) Proclisis

- a. $[_{FinP} \text{ **que/se**+Fin } [_{CP} \text{ } t_{que/se} [_{TP} \text{ **cl**+T } [_{AspP} \text{ V+v+voice+Asp } [_{VoiceP} \text{ } t_{cl} \text{ } t_{voice} \text{ } [_{VP} \dots]]]]]]]]$
- b. $[_{FinP} \text{ **não**+Fin } [_{\Sigma P} \text{ } t_{n\tilde{a}o} \text{ } [_{TP} \text{ **cl**+T } [_{AspP} \text{ V+v+voice+Asp } [_{VoiceP} \text{ } t_{cl} \text{ } t_{voice} \text{ } [_{VP} \dots]]]]]]]]$

¹¹ This is not the case with *só*, which can precede or follow negation, depending on scope.

- c. [_{FinP} **já**+Σ+Fin [_{ΣP} t_{já} [_{TP} **cl**+T [_{AspP} t_{já} [_{VoiceP} **V+v+Voice** [_{VP} ...]]]]]]]
- d. [_{FinP} **whP** Fin [_{TP} **cl**+T [_{AspP} V+v+voice+Asp [_{VoiceP} t_{cl} t_{voice} [_{VP} ...]]]]]]]

Note, crucially, that in (27a-b), the verbal complex raises to T, whereas in (27c) it does not as the adverbial *já* blocks this movement (because it is both a head and a phrase). This will be crucial in accounting for the special behaviour of this class of triggers in non-finite uninflected contexts.

3 The curious behaviour of European Portuguese uninflected verbs

3.1 Clitic placement with uninflected infinitives

As already noted, with finite inflected verbs, wh-movement always triggers proclisis, in matrix and embedded clauses. In such contexts, enclisis is strongly unacceptable and this follows, on the Anti-V2 account, if wh-phrases must transit through spec FinP, satisfying the edge condition and blocking verb movement to Fin:

- (28) *Como { te= chamás / *chamás =te }?*
 how yourself= call.pres.2SG call.2SG =yourself
 Lit. ‘What do you call yourself?’

- (29) *Não sei como { te= chamás / *chamás =te }.*
 NEG know.1SG how yourself= call.2SG call.2SG =yourself
 Lit. ‘I don’t know what you call yourself.’

Non-finite questions with an uninflected infinitive are notably different as both proclisis and enclisis become possible (Martins 2013a: 2283):¹²

- (30) *Não temos a quem { nos= queixar / queixar =nos }.*
 NEG have.1PL DAT who REFL.1PL= complain complain. = REFL.1PL

¹² It is not the case that enclisis and proclisis alternate freely with uninflected infinitives. In enclisis/mesocclisis contexts, proclisis is not possible with uninflected infinitives (see Martins 2013a: 2278-2279).

- (i) { Amar =te / *te amar } é fácil.
 love.INF =2SG 2SG= love.INF is easy
 ‘Loving you is easy.’

‘We don’t have anyone to complain to.’

- (31) *Ficámos mesmo sem saber o que {lhes= dizer / dizer=lhes}*
 remained really without know the what them.DAT= say say =them.DAT
 ‘We ended up really not knowing what to say to them.’

As also noted by Raposo and Uriagereka (2008), this is a more general pattern with uninflected infinitives. With the following proclisis triggers, enclisis becomes possible with uninflected infinitives: (i) (prepositional) complementisers like *de* ‘of’ *para*, *por* ‘for’ (28) and (ii) negation (29), both strict proclisis triggers with finite verbs:

- (32) [*Para* { *a= ver / vê =la* } *outra vez*], *far-ia tudo*.
 for her= see.INF see.INF =her another time do-COND.1SG everything
 ‘In order to see her one more time I would do everything.’
- (33) [*Não* { *a= convidar / convidá =la* } *para a nossa festa*]
 NEG her= invite.INF invite.INF =her for the our party
ser-ia uma boa ideia.¹³
 be-COND.3SG a good idea
 ‘Not to invite her to our party would be a good idea.’

(Raposo and Uriagereka 2008: 677, 669)

Note also the behaviour of embedded Y/N questions, which are similar except that enclisis is more common here, unlike in finite contexts (see Martins 2013a):

- (34) *Não sei se {me= expliquei / *expliquei =me} bem*.
 NEG know.1SG if REFL.1SG=explained.1SG explained.1SG= REFL.1SG well
 ‘I don’t know whether I explained myself well.’
- (35) *Não sabemos se dizer= lhe a verdade*.
 NEG know.1PL if say= 3SG.DAT the truth
 ‘We don’t know whether to tell him the truth.’ (Martins 2013a: 2284)

¹³ Note that enclisis often results in morphological changes to the clitic and/or verbal host. I abstract away from these patterns here, assuming they occur post-syntactically, as sketched in Section 2.2.

As Raposo and Uriagereka (2008) further note, not all non-finite verbs pattern this way – inflected infinitives pattern largely like finite verbs in not allowing enclisis in the presence of a proclisis trigger (see also Martins 2013a: 2284-2287):

- (36) *[Para {a= ver-mos /*ver-mo =la} outra vez],*
 for her=see.INF-1PL see.INF-1PL =her another time,
far-íamos tudo.
 Do-COND.1PL everything (Raposo and Uriagereka 2008: 683)
 ‘In order for us to see her again, we would do anything.’

We will consider in Section 4 why only uninflected infinitives permit enclisis in the presence of what is otherwise a proclisis trigger, but for now it is important to recall that 3sg inflection is null with infinitivals. This makes the distinction between inflected and uninflected infinitives opaque in some cases. As Raposo (1987) shows, fronted wh-phrases are incompatible with inflected infinitives, so in the case of embedded wh-clauses, we can be sure that we are dealing with a verb which lacks inflection. Conversely, overt subjects are usually only possible with inflected infinitives in EP (Sheehan 2018). For this reason, it is difficult to check the behaviour of subject QPs with uninflected infinitives. There is one context, however, where uninflected infinitives surface with an overt subject: the ECM complements of causatives. As Martins (2013a: 2280) shows, only proclisis is possible in such contexts (somewhat surprisingly):

- (37) *Os soldados mandaram ninguém { se= mexer /*mexer =se}*
 The soldiers ordered nobody REFL.3= move move =REFL.3
 ‘The soldiers ordered for nobody to move.’

I leave open the status of these ECM complements in which clitic placement appears to function as it does in finite clauses.¹⁴

¹⁴ Another issue not analysed here is the status of subordinating *a* which, unlike the prepositional complementisers *de*, *por*, *para*, never triggers proclisis and is transparent for clitic climbing, suggesting it is not a realisation of C:

- (i) *Uma madrugada despertaram =no a abaná=lo com força*
 one early.morning woke.3PL =him A shake=him with force
 ‘One early morning, they woke him up by shaking him forcefully.’ (Martins 2013a: 2280)

These peripheral cases notwithstanding, it is generally the case with XP proclisis triggers, negation and complementiser/prepositional subordinators that enclisis is optionally available where an infinitive is uninflected, unlike that which was observed in Section 1 for finite contexts. Crucially for us, though, as Martins (2013a: 2283, 2284) notes, head-like adverbial triggers pattern differently. With uninflected infinitives, if an adverbial head proclisis trigger is present, then enclisis is ruled out:

(38) *Estamos sem saber o que ainda/também*

are.1PL without know the what still/ also

{*lhes*= contar / *contar =*lhes*}

them.DAT= tell.INF tell.INF =them.DAT

‘We are left not knowing what to still/also tell them.’ (Martins 2013a: 2283)

(39) *Não sabemos se só {lhe= falar /*falar =lhe} amanhã*

NEG know.1PL if only 3SG.DAT= speak.INF speak.INF =3SG.DAT tomorrow

‘We don’t know whether only to speak to him tomorrow.’ (ibid: 2284)

(40) *Apesar de já {se= encontrar /*encontrar =se} aberto ao público...*

despite of already SELF= find.INF find.INF =SELF open to.the public

‘Despite already finding itself open to the public...’¹⁵

In these examples, an adverbial head proclisis trigger surfaces in addition to another proclisis trigger. In all cases, adding an adverbial trigger gives rise to obligatory proclisis with uninflected infinitives. Clearly, then, something about these adverbial head proclisis triggers is inherently incompatible with enclisis.¹⁶

Table 1: proclisis triggers with uninflected infinitives

¹⁵ An anonymous reviewer points out an exception to this where *só* ‘only’ occurs without another proclisis trigger:

(i) *Eles acham que é possível [{ só lhe= contar / só contar=lhe} parte da verdade]*

They think that is possible only 2SG.DAT tell only tell =2SG.DAT part of.the truth

‘They think that it’s possible to only tell him part of the truth.’

This suggests that *só* can maybe also function as an XP trigger. As noted in Section 1.2 and 2.3 *só* differs from the other adverbial head proclisis triggers also in other respects. I leave this interesting matter to future research.

¹⁶ I am simplifying somewhat here. Martins (2013a: 2284) also notes that *nunca*, *jamaiz* and *pouco* are also incompatible with enclisis in non-finite contexts. I will put these adverbs to one side here. It is not clear whether they function as heads or not in EP and their syntax requires further investigation.

Proclisis trigger	Finite verbs	Uninflected infinitives
Fronted wh phrase	Proclisis only	Proclisis/enclisis
Complementiser (<i>de</i> ‘of’, <i>para</i> ‘for’, <i>por</i> ‘for’)	Proclisis only	Proclisis/enclisis
Negation (<i>não</i> ‘not’)	Proclisis only	Proclisis/enclisis
Asp/Q heads (<i>já</i> , ‘already’ <i>ainda</i> ‘still’, <i>só</i> ‘only’, <i>também</i> ‘also’)	Proclisis only	Proclisis only

There are two puzzles that must be explained here. First, it must be explained why enclisis becomes possible with almost all proclisis triggers in non-finite contexts. Second, we must explain why adverbial head proclisis triggers pattern differently in being incompatible with enclisis.

3.2 Raposo & Uriagereka's (2008) 'low fusion' proposal

Raposo and Uriagereka (2008) note that uninflected infinitives can always host clitics in restructuring contexts (as is the case also in Spanish, Italian and many other Romance varieties).

- (41) a. *Vou* **=te** *ajudar.* / *Vou* *ajudar***=te**
 go.1SG =you help.INF go.1SG help=you
 ‘I’m going to help you.’
- b. *Estou* **=te** *a chamar* / *estou* *a* *chamar***=te**
 am =you to callI am to call=you
 ‘I am calling you.’

In such contexts, we see optionality between the climbed and non-climbed options. To capture this, Raposo and Uriagereka posit optional ‘low fusion’ whereby a clitic can optionally cliticise to a non-finite uninflected verb rather than raising to its usual high position.

Fleshing out their proposal in our terms, let us assume that low infusion occurs where the clitic (with its [uT] feature), moves to adjoin to *v* forming a verbal cluster with the verb. Once the clitic and the verb have undergone morphological merger, the two can continue to

move as a single unit with the derivation converging as long as the clitic + verb can raise high enough to value the clitic's [uT] feature. Assuming that the complements of restructuring verbs are at least as large as TP (see Kayne 1991 for a compatible proposal), the derivation will converge in such cases, as the non-finite verb plus clitic can raise to the embedded T:

(42) *Estou a [TP PRO ver+v+te+Voice+Asp+T ...*

Note that low cliticization in restructuring contexts is potential evidence against the high base generation of clitics and in favour of the view that clitics at least can be base generated in argument positions.¹⁷ In cases like (42), *ver+v+te* raises to T, to satisfy the clitic's [uT] feature. The alternative, of course, is for the clitic to raise to adjoin to the matrix T, leading to 'clitic climbing' (see Kayne 1991 for an account along these lines).

3.3 Evidence for the importance of tense

As already noted, Raposo and Uriagereka 2008 note that inflected infinitives do not permit enclisis in the presence of proclisis triggers, unlike uninflected infinitives:

(43) [Para {a= ver-mos /*ver-mo =la} outra vez],
 for her= see.INF-1PL see.INF-1PL =her another time,
 far-íamos tudo.
 do-COND.1PL everything (Raposo and Uriagereka 2008: 683)
 'In order for us to see her again, we would do anything.'

To account for this, Raposo & Uriagereka posit the following condition:

(44) Condition on determiner clitic fusion (Raposo and Uriagereka 2008: 672)

A determiner clitic cannot fuse to the "agreeing edge" (i.e., the right edge, in Romance) of a verbal form displaying agreement.

I assume that (44) holds because where a clitic undergoes low attachment to the verb, the clitic intervenes between *v* and Voice and this blocks the insertion in the morphological

¹⁷ Other evidence for this comes from restrictions on clitic movement like those described by Kayne (1975, 1989), Rouveret & Vergnaud (1980) and Abeillé, Godard & Sag (1998). These restrictions are challenging to model if clitics do not originate in thematic positions.

component of verbal forms realising Voice and Aspect. This rules out any inflected verbs in EP. There are other contexts where the verb is not inflected, however, and low fusion is still blocked, which are not discussed by Raposo and Uriagereka (2008). I argue that what all these contexts have in common is a lack of embedded tense, as predicted by our approach to clitics.

There is strong evidence from clause union verbs that low fusion is only possible in contexts where T is present. In EP, the verb *mandar* ‘order/have’ can select clause union complements (Gonçalves 1999) permitting long passivisation of the object:

(44) *Esta sondagem foi mandada fazer pelo Professor Duarte.*

this survey was had do by.the professor Duarte

Lit: ‘This survey was had do by Professor Duarte.’

[based on an online judgement task on a 5-point Likert scale, mean rating = 4.1/5, n=18]

In these contexts, the infinitive cannot host any clitics in EP, as is well known:

(45) *Eu {mandei=a comer / ??mandei comê =la aos meninos.*

I had =it eat.INF had eat.INF =it to.the kids

‘I had the kids eat it.’ (Costa & Gonçalves 1999: 63)

This follows from the low fusion approach because, in such contexts, the non-finite verb is contained in a reduced complement which lacks tense (and probably also Voice). While the causative verb raises to matrix T, the non-finite verb cannot and so the clitic is unable to discharge its [uT] feature if it cliticised to the non-finite verb. For this reason, its only option is to raise to matrix spec TP and cliticise to the main causative verb (with enclisis/proclisis being determined in the same way it always is with finite verbs – see Sections 1-2).

Non-agreeing gerunds also block low fusion in EP, both in restructuring contexts and elsewhere, as do past participles:

(45) a. {Tenho =o visto / *tenho visto=o muito recentemente.

have.1SG =him seen have.1SG seen=him much recently

b. Entretanto, {ia =se distanciando / *ia distanciando=se da família ...

meanwhile went =self distancing went distancing=self from.the family

(Martins 2013a: 2292)

As an anonymous reviewer notes, we can assume, based on syntactic and semantic criteria, that these embedded contexts also lack T (e.g. the impossibility of disjoint temporal adverbials modifying the matrix and embedded auxiliary/verb).

So, actually, it is only uninflected infinitives in EP which allow low fusion (note that there are minimal differences here between EP and other Romance languages in this respect). The effect may be attributed to the fact that low fusion requires (a) an uninflected verb and (b) an embedded T projection. The result is a pattern whereby uninflected infinitives will generally permit enclisis as long as the verbal complex containing the clitic can go on to raise to T. Where this is blocked it is either because T is absent from an embedded clauses (i.e. in clause union, gerund or past participle contexts) or because movement of the verb to T is blocked for some other reason.

Raposo and Uriagereka (2008) propose that low fusion of this kind is possible not only in restructuring contexts but also elsewhere and that this provides an account for optional enclisis with uninflected infinitives, as outlined in the following Section.

4 Putting it all together: a unified analysis of the patterns

4.1 Optional enclisis with uninflected infinitives

Proclisis/enclisis optionality follows if low fusion is available with uninflected infinitives in the following kinds of contexts:

- (46) *Não temos a quem {nos= queixar / queixar =nos}.*
 NEG have.1PL DAT who REFL.1PL= complain.INF complain.INF = REFL.1PL
 ‘We don’t have anyone to complain to.’

In examples like (46), either the clitic raises to v and undergoes low fusion with *queixar* (47a), or the clitic raises to adjoin directly to T (47b), resulting in proclisis:

- (47) (a) [_{VoiceP} V+v+voice+CI [_{vP} t_v [_{vP} t_v t_{Cl}]]]
 (b) [_{FinP} t_{whP} Fin [_{TP} CI+T [_{AspP} V+v+voice+Asp [_{VoiceP} t_{cl} t [_{vP} ...]]]]]]

Crucially, where the clitic raises to adjoin to v, it must still discharge its [uT] feature. This causes the whole verbal complex plus clitic to raise to T (as argued for in Section 3.3). Note

that, in such cases, the whP will still satisfy Fin's edge feature on its way to a higher position, but in this context, the result will be enclisis, not proclisis (because of low fusion):

(48) $[_{FinP} \mathbf{t_{whP}} \text{Fin} [_{TP} \mathbf{V+v+CI+voice+Asp+T} [_{AspP} \mathbf{t_{Asp}} [_{VoiceP} \mathbf{t_{cl}} \mathbf{t} [_{vP} \mathbf{t_v} [_{VP} \mathbf{t_v} \mathbf{t_{cl}}]]]]]]$

The availability of low fusion therefore explains the availability of enclisis in the presence of proclisis triggers, as Raposo & Uriagereka (2008) note.

4.2 No low fusion with adverbial head proclisis triggers

Now recall that low fusion (i.e. enclisis) is blocked with uninflected infinitives where the class of adverbials head proclisis triggers are present:

(49) *Apesar de já {se= encontrar /*encontrar =se} aberto ao público...*
 despite of already SELF= find.INF find.INF =SELF open to.the public
 'Despite already finding itself open to the public...'

Recall the structure in (27) repeated here as (50) which represents what happens with these adverbials in finite contexts:

(50) $[_{FinP} \mathbf{já+\Sigma+Fin} [_{\Sigma P} \mathbf{t_{já}} [_{TP} \mathbf{CI+T} [_{AspP} \mathbf{t_{já}} [_{VoiceP} \mathbf{V+v+Voice} [_{vP} \dots]]]]]]]]$

In (50), the adverbial *já* is base-generated in Asp as a minimax category. This is the position generally agreed to house aspect so this positioning of *já*, 'already' and *ainda* 'still' seems uncontroversial. It is less clear why *só* 'only' and *também* 'also' should occupy this position but let us assume that they either occupy the same position or perhaps an adjacent head position, given their uniform behaviour with the aspectual adverbs. In clauses lacking these adverbs, we have been assuming that the finite verb raises to Asp in EP. It is apparent in (50) that the base-generated position of these adverbs blocks verb movement to Asp or higher. This means that, even though these adverbs do not themselves move through T, they nonetheless block verb-movement to T. Crucially, verbs are not minimax categories, they are heads, and so they can only move subject to the Head Movement Constraint. The presence of an adverb in Asp which has the status of both a phrase and a head blocks verb movement to T.

Now consider the implications of this analysis for uninflected verbs which, in principle, permit low fusion. On our analysis, low fusion is predicted to be incompatible with these Asp head proclisis triggers simply because the clitic cannot check its [uT] feature in such contexts. Nothing prevents the clitic from raising to v as a head and fusing with the verbal complex. However, the verbal complex plus clitic can only ever raise to a position below Asp; it cannot reach T. In cases where something else satisfies Fin's edge feature, these adverbs still raise to Σ , but verb movement to T is always blocked, nonetheless, because of the base position of these adverbs:

$$(51) \quad *[\text{FinP } \mathbf{de} + \text{fin} [\text{CP } t_{\text{de}} [\Sigma \text{ } \mathbf{j\acute{a}} + \Sigma [\text{TP } T [\text{AspP } t_{\text{j\acute{a}}} [\text{VoiceP } \text{encontrar} + \text{v} + \mathbf{se}_{[\text{uT}]} + \text{voice} [\text{vp} \dots]]]]]]]]]$$

In such cases, no matter how Fin's edge feature is satisfied, aspectual/focalizing adverbials will never be compatible with low fusion as the clitic's [uT] feature will always go unvalued. This problem does not arise in instances of proclisis as, in this case, the clitic raises to T, directly satisfying its [uT] feature. The adverb then raises to Σ . In (52) a C-head the satisfies Fin's edge feature, resulting in proclisis.

$$(52) \quad [\text{FinP } \mathbf{de} + \text{Fin} [\text{CP } t_{\text{de}} [\Sigma \text{ } \mathbf{j\acute{a}} + \Sigma [\text{TP } \mathbf{se}_{[\text{uT}]} + T [\text{AspP } t_{\text{j\acute{a}}} [\text{VoiceP } \text{encontrar} + \text{v} + \text{voice} [\text{vp} \dots]]]]]]]]]$$

There is a minimal contrast here with negation, which is compatible with both enclisis and procisis with uninflected infinitives, meaning, in our terms, that it is compatible with low fusion:

$$(53) \quad [\text{N\acute{a}o} \{ \mathbf{a} = \text{convidar} / \text{convid\acute{a}} = \mathbf{la} \} \text{ para a nossa festa}]$$

NEG her= invite.INF invite.INF =her for the our party

ser-ia uma boa ideia.¹⁸

be-COND.3SG a good idea

'Not to invite her to our party would be a good idea.' (R&U: 2005:669)

¹⁸ Note that enclisis often results in morphological changes to the clitic and/or verbal host. I abstract away from these patterns here, assuming they occur post-syntactically, as sketched in Section 2.2.

This follows from our analysis because, unlike aspectual adverbials which originate below T, negation originates above T (Zanuttini 1997) and so fails to block movement of the verbal complex to T:

(42) [_{FinP} **não**+Σ+Fin [_{ΣP} t_{não} [_{TP} V+V+**Cl**+voice+Asp+T [_{AspP} t_{Asp} [_{VoiceP} t_{cl} t [_{vP} ...]]]]]]]

For this reason, negation is compatible with low fusion meaning that it allows both proclisis and enclisis with uninflected verbs. The same applies to complementisers, which are also (uncontroversially) base generated above T, in a position just below Fin.

To summarise: **enclisis** is possible (in addition to **proclisis**) with uninflected infinitives in the presence of: Wh-phrases, complementisers (and *se* ‘if/whether’), and negation because low fusion is possible (Raposo and Uriagereka 2008). We do not find this optionality with adverbial head proclisis triggers because they block movement of the verbal complex to T and so the clitic cannot satisfy its [uT] feature.

5 Conclusions

In this paper, I have argued that EP clitic placement is regulated by a syntactic anti-V2 condition which requires either head movement to Fin or phrasal movement to spec FinP, but not both (developing the proposal by Fernández-Rubiera 2009, 2010). Clitics originate in argument positions and either raise (as minimax categories) to adjoin to T or fuse with a non-finite verb and undergo head-movement to T as part of the verbal cluster. Proclisis results where the clitic raises to T and something other than the verb satisfies the anti-V2 requirement. Enclisis, on the other hand, results from either (a) clitic movement to T and subsequent verb movement to Fin or (b) low fusion of the clitic with the verb inside vP and then movement of the verbal complex to T. Low fusion is possible only with uninflected infinitives in a context with a low T projection for principled reasons: clitics must discharge their [uT] feature. For the same reason, even with uninflected infinitives, adverbial head proclisis triggers block movement of the verb+clitic cluster to T, making low fusion impossible.

The broader implications of all of this are wide-reaching. It is not possible to model enclisis or proclisis as a prosodic effect because proclisis alternates freely with enclisis in the contexts described. The connection between these contexts and those in which optional clitic climbing is possible strongly suggest that a morphosyntactic account of EP clitic placement is

required. Clitic placement in EP has been shown to be sensitive to: (i) verbal inflection, (ii) the presence of Tense, and (iii) the syntactic height of triggers, so, it is best modelled as a morphosyntactic side-effect of an Anti-V2 requirement whereby movement to spec FinP competes with verb movement to Fin.
