Three Fates or, some say, Io the sister of Phoroneus, invented five vowels of the first alphabet, and the consonants B and T

Alphabeta Meminerunt Syllabaria
(rudiments of syllabaries in alphabets)

Before alphabets ever formed, there were syllabaries.

Certainly we have some legends about those times, and those legends happen to be accurate.

Definitely five vowels and two consonants (from Hyginus's Greek Myths and Robert Graves's Greek Myths (the same title, but in newer version it is clearer)) could be only useful to transmit texts if they were the structure of syllabary. Link to Graves may raise some eybrows, but my research has discovered, that his version is closer to reality than any other one, which raises the question of whether he was just a poet.

A BA DA
E BE DE
I BI DI
O BO DO
U BU DU

And naturally because each syllable had its own symbol, we had something like

A BA DA
E VE ŽE
I MI NI
O PO TO
U FU ŠU

Those who know some Japanese will understand:
T of Ta turns Ch with I and Ts with U
H of Ha is sometimes W, and with U it's F
different syllabary, but similar features.

Let's look at them as they would look being a syllabary,
syllabaries depict syllables with single glyphs:

A B D
E V Ž
I M N
O P T
U F Š

ço in general

A B D
E F Γ
I M Λ
O П T
U 8 S

I? (F is read as V, as they do in hebrew,
Γ the G is read as Ж, which is in that very position)
but then does S sound as Ш? Or does that Γ the G sound as Z, as in greek?
(I had to stretch this one, but 8 is some ancient european form of F)

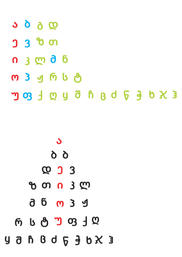
Double shapes for labials and single shapes for linguals, which is symbolically really truly very deep

And.. it's too difficult to read text written in such set for it to be convenient.

If you think that arabic doesn`t have vowels, consider kurdish.

If you think that hebrew doesn`t have vowels, think yiddish.

If you want to read more about it, aeiou.nu



But texts composed of these 20 letters can be read mostly without much trouble:

Unplesedented availabiliti of infolmation makes even the most sakled elements of human knouledge available, sutj as bild language, language of gods, language konsisting onli of vouels, fills the bogomilik himn AEIOU uith meaning and kontlaposes it to (uho knous, maibe even moːe ansient, koming flom that aeon, uhen B uas the filst lettel, as it is in Tolah, Kolan and Ogham) judaik EIOUA ol IEOUA, flom uhikh it is one step to IEAOU, the alkhaik dessending pentatonik.

Some words are still puzzling, which might explain why they would want to add additional symbols to this coherent structure of gradual descent from voiced plosives to voiceless fricatives.

J in this structure is voiced H (or fricative G)
N in this structure is closer to ŋ

But now let's return to the idea of labials being double (as lips are two) and lingual being single (as tongue is one)
B D
F Γ
M Λ
П T
that is pretty much Greek. That may tell that Greek was the earliest alphabet. Or, at least that these glyphs, mostly known from greek, lay at the foundation of the alphabets.
Even their Δ aligns with ᵬ
Archaic alphabets didn't have the fifth line, but 8 and S(and also ϟ) and also Φ P[r] could be added to this collection of correlations. Could they be dialectal? ɔ is read as both p and f, ɲ is read as both t and θ, not sure about R, but it is also in the P-line, so it's possible.
Latin P[p] wouldn't work, but it would work well with the other pairing story:
Б B [b v]
Γ Z [g z]
Λ N [l n]
P Φ [p f]
C S [k s]
Yet this simmetry is a little less in the alphabetic order than the previous one, thus I suppose this layer of complexity to have appeared later.
Also because myths speak of labials and linguals only.

It is still predominantly Greek, with other writing systems offering very few examples, so labial-lingual symmetry can be somewhat noticed in hebrew:
single ד and double ב and single ג and double ɲ, and in that light L-like ג makes sense, maybe also that L and N were the same letter once.

And longer-shorter simmetry can be seen in such examples as K Ж and Ц Щ, and whether they're rudiments of that symmetry or accidental or if those who introduced them only subconsciously followed the previous patterns, it is very hard to tell.

what should I do with the counter-examples such as V and X?
I can see X[h] as double C
and the X[ks] as c[k] and c[s] and it may even tell that ɔ could stand for k, while c was s, or visa versa.
And what about V? it is literally half the X (be they 5 and 10 or 4 and 8)
another obvious exception is W being double V, but then this pair aligns into the long-short symmetry.
And in that context W is double V, not double U (double ю never made sense to me)
so, basically pairs not laying into either of the two symmetries are WU and XV, both are in the final line, past T, in symbolic afterlife where everything is in reverse (not growth but decay, not ΛMN, but uvw (not the same order whichever way you look at it, but the order varies between national alphabets, and position of M is still a huge question (the direct inversion would sugest MΛN instead of MNΛ)))

V and X could be math, being the opposite of language and thus reflecting it,
just as – is not minus in language, but rather = or +
