

Absolutive agreement failure and the flavors of T/Infl⁰ in Mam

Noah Elkins, Haverford College

nelkins@haverford.edu

1 Introduction

The Mayan languages, which display head-marking ergative-absolutive alignment, all share roughly the same morphological template in their verbal complex, but a major point of variation is the linear position of absolutive morphology. Since Tada (1993), the Mayan languages have been grouped into two major categories: “high-ABS” languages in which absolutive is expressed pre-verbally, and “low-ABS” languages in which absolutive is expressed post-verbally. This division is not simply descriptive: the parameter has deep implications for various syntactic and semantic properties, including $\bar{A}$ -extraction asymmetries, case-marking possibilities in reduced clauses, patterns of syntactic binding, and the definiteness of transitive objects. In recent years, growing attention has been paid to identifying these correlates of the high-/low-ABS divide in Mayan.

Within this research program, Mam (iso 639: mam), a Mayan language traditionally classed as high-ABS, has been shown to have significant inter-dialectal variation with respect to their patterns of absolutive case assignment, particularly in the Northern dialect area (England 2017). In San Juan Atitán Mam (Scott 2023) and Todos Santos Mam (Elkins 2023), for instance, pre-verbal ABS morphology does not faithfully cross-reference the ϕ -features of transitive objects. In a heritage variety of San Sebastián Mam (Myers 2025), there does not appear to be any pre-verbal agreement for transitive objects at all. These Mam varieties, then, have descriptive dissimilarities from other high-ABS languages.

In this squib, I continue to explore Mam dialectal variation in ABS case assignment by exploring what I term the *null completive construction* in Todos Santos Mam. In a typical declarative clause, absolutive arguments (which may be *pro*-dropped) are cross-referenced with pre-verbal absolutive case morphology (called Set B in the Mayanist tradition; ergative/possessive morphology is called Set A). This is shown in (1a) with the B1S morpheme *chin*. In the null completive construction,

however, there is no (overt) aspect morpheme present in the clause; when this happens, absolutive (Set B) agreement is impossible. To express the ϕ -features of the absolutive pronominal argument, an overt pronoun must be pronounced in argument position (*qen* ‘1SG.PRON’ in 1b).

- | | |
|---|---|
| <p>(1) a. O chin jaw tz’aq
 COM B1S DIR fall
 ‘I fell’</p> | <p>b. (*Chin) jaw tz’aq *(qen)
 B1S DIR fall 1SG.PRON
 ‘I fell’</p> |
|---|---|

I call the construction in (1b) the null completeive construction because I argue that clauses like this, with no (overt) aspect, do still have an aspect morpheme, however it happens to lack phonological content. The use of this morpheme $\emptyset$ refers to a past completeive action, similar in interpretation to the overt past completeive morpheme *o* ‘COM’.

The goal of this squib is to understand the point of variation between clauses like (1a) and (1b) in Todos Santos Mam. My analysis of the null completeive construction (which as far as I am aware is only attested in this dialect) rests on two key assumptions, each with cross-linguistic support. The first is that in high-ABS Mayan languages, the locus of Set B agreement is T/Infl⁰, the head also responsible for expressing aspect morphology (Coon, Mateo Pedro, and Preminger 2014 *et seq.*). The second assumption, following a suggestion by Armstrong (2017), is that T/Infl⁰ can either host a $[u\phi]$ probe or lack one. I ultimately draw the conclusion that Set B agreement in the Mayan languages operates as a distinct mechanism from case-licensing proper.

2 Language background

2.1 Basics of Mam morphosyntax

Mam is a Mamean-branch Mayan language spoken predominantly in Guatemala and Mexico by around 600,000 individuals (Pérez Vail 2014). The dialect under discussion here is Todos Santos Mam (henceforth TSM), a member of the Northern Mam dialect area spoken in and around the municipality of Todos Santos, Cuchumatán, Huehuetenango, Guatemala.

TSM displays baseline VSO word order (England 1991), although elements may be $\bar{A}$ -extracted

to pre-predicate position (i.e. for *wh*-questioning and focus, and relativization; Aissen 1992). TSM has ergative-absolutive alignment, with case relations expressed on the predicate (head-marking); post-verbal arguments may be null/*pro*-dropped (see also Minkoff 2000). The verbal complex containing several elements: first is aspect/mood (AM) morphology, followed by an optional directional auxiliary, followed last by the verb stem itself. TSM is classed as a high-ABS language (Tada 1993, Coon et al. 2014), with absolutive (Set B) morphology preceding ergative (Set A) morphology within the verbal complex. The verb stem itself may take additional suffixes that track transitivity, as well as person-marking enclitics (England 1983).

(2) Mam verbal template

AM – **SET B** – DIR – **SET A** – VERB STEM – SUFF – ENCL

- (3) Ma **Ø**-kub' **n**-b'iyó-'n *pro*_[1SG] jel b'alam
 PROX B2/3S-DIR A1S-kill-DS CLF jaguar
 'I killed the jaguar'

TSM is one of several innovative Northern Mam dialects to have what Scott (2023) has termed “default Set B”, a setup in which, while Set B agreement faithfully reflects the ϕ -features of intransitive subjects (4a), Set B for transitive objects is uniformly the “default” B2/3S morpheme; the ϕ -features of pronominal objects are expressed by means of an overt pronoun in object position (4b). Default Set B is the most common strategy of object marking in TSM. A situation more canonically associated with high-ABS languages, in which there is faithful cross-referencing of transitive objects by Set B (indeed the only pattern available in more conservative dialects of Mam such as Ixtahuacán Mam; England 1983) is also grammatical (4c), but in TSM this is associated with an extremely formal register, only appropriate, for example, when giving a speech.

(4) Patterns of Set B agreement in TSM

- a. Ma **chin** jaw tz'áq *pro*_[1SG]
 PROX B1S DIR fall
 'I fell'

Intransitive: faithful Set B

- b. Ma **tz'**-ok t-pju-'n Miguel **na'**ya
 PROX B2/3S-DIR A2/3S-hit-DS Miguel 1SG.OBJ.PRON

‘Miguel hit me’ (=4c)

Transitive: default Set B

- c. Ma **chin** ok t-pju-’n Miguel *pro*_[1SG]
PROX B1S DIR A2/3S-hit-DS Miguel

‘Miguel hit me’ (=4b)

Transitive: formal register

Finally, TSM is syntactically ergative (Aissen 2017): $\bar{A}$ -extraction of ergative arguments is impossible (5a). An antipassive must be used to “circumvent” this restriction. The antipassive involves demoting the thematic object to an oblique phrase headed by a relational noun/preposition; the thematic agent is cross-referenced by means of Set B. Antipassive clauses are formally intransitive: the verb bears an intransitive suffix, and there is no Set A on the predicate (5b).

(5) Mam syntactic ergativity ameliorated by antipassive

- a. *Al_i ma Ø-kub t-b’iyo-’n t_i jel b’alam?
who PROX B2/3S-DIR A2/3S-kill-DS CLF jaguar
Cannot mean ‘Who killed the jaguar?’
- b. Al ma Ø-kub’ b’iyoo-n [_{OBL} t-e jel b’alam]?
who PROX B2/3S-DIR kill-AP A2/3S-RN:PAT CLF jaguar
‘Who killed the jaguar?’

Like many authors, I assume an object raising account of syntactic ergativity in high-ABS languages like Mam (Coon et al. 2014 *et seq.*, building on Campana 1992, Ordóñez 1995, Bittner and Hale 1996, Aldridge 2004; see Coon and Royer 2025 for an overview). While space precludes a thorough elaboration of this account, it crucially proposes that transitive objects consistently raise to a position above transitive subjects, where they serve as interveners between their subjects and any $\bar{A}$ -probes on higher heads like C⁰ (6). This is typically conceptualized as A-movement driven by an [EPP] feature on *v*/Voice⁰.¹ A number of additional morphosyntactic and semantic correlates of object raising have been presented in recent literature (e.g. Little 2020, Royer 2022, Elkins 2025, Myers 2025, Coon and Royer 2025), which have further strengthened this account.²

¹ Authors vary in the precise mechanism(s) by which object raising leads to the ineffability of extracting ergative subjects, though nothing in this squib hinges on this (see Coon et al. 2014, Coon, Baier, and Levin 2020 for feature-based approaches, and Tollan and Clemens 2022 for a processing-based approach); these works still presuppose (or present argumentation in favor of) object raising. See also Deal (2016) and Polinsky (2016) for alternative approaches in which the restriction involves properties of the ergative argument itself.

² Object raising (at least in Mam) does not reflect a change in word order. I assume, following Elkins (2025), Scott

2.2 Reanalysis in the TSM aspectual system

The aspectual system in TSM is notable for having undergone a significant reanalysis over the last few decades. The aspectual system today has diverged not only from more conservative Northern Mam varieties such as Ixtahuacán Mam (England 1983), but also from how it was described in the late 1960's by Una Canger (Canger 1969). The extent of the reanalysis is as follows. In more conservative dialects, there are four aspectual morphemes, two of which show clause-type-based allomorphy. England uses the term *dependent* to describe various types of embedded clauses; building off this terminology, I use the term *independent* to refer to matrix clauses. The other two aspects (incompletive *n-* and potential (*ok*)...-*l*) do not show this clause-type-based alternation.

	independent	dependent	meaning
(7) Ixtahuacán Mam aspectual system	<i>o</i>	∅	completive
	<i>ma</i>	<i>x-</i>	proximate
		<i>n-</i>	incompletive
		(<i>ok</i>)...- <i>l</i>	potential

The completive *o* and the proximate *ma* are only possible in matrix clauses in Ixtahuacán Mam. In embedded/dependent clauses, the former is realized as ∅ and the latter is realized as *x-*. This is very often seen in cleft-like constructions where material appears to the left of the aspect morpheme. Importantly, this alternation is purely allomorphic, and not interpretational: regardless of how it is expressed, the completive aspect is associated with a more distant past completive event (8), and the proximate aspect is associated with a recent completive event (9).

(8) Allomorphs of the completive aspect (England 1983:162)

- a. O chin jaw tz'aq=a
 COM B 1 S DIR slip=1 S
 'I slipped (a while ago)'

(2023) and Little (2020), that object raising in Mam is *rightward*, which preserves VSO; it could also be leftward but covert: nothing in this squib hinges on this. In general, it has long been understood that basic word order in a given Mayan language is not correlated with its absolutive parameter (Coon et al. 2014, Coon, Baier, and Levin 2021).

- b. T-uj b'ee in jaw tz'aq=a
 A2/3S-RN:in road COM_DEP.B1S DIR fall=1S
 'It was in the road that I slipped (a while ago)' ($\emptyset$ + *chin* = *in*)

(9) Allomorphs of the proximate aspect (England 1983:162)

- a. Ma chin jaw tz'aq=a
 PROX B1S DIR slip=1S
 'I slipped (just now)'
- b. T-uj b'ee xhin jaw tz'aq=a
 A2/3S-RN:in road PROX_DEP.B1S DIR fall=1S
 'It was in the road that I slipped (just now)' (*x-* + *chin* = *xhin*)

In TSM (and other innovative Northern Mam dialects like San Juan Atitán Mam; see Scott 2023:57-64), both dependent aspect morphemes have been reanalyzed as matrix aspects with distinct aspectual interpretations. That is, both $\emptyset$ and *x-* are possible in both matrix and embedded clauses, and so these dialects do not exhibit clause-type-based aspectual allomorphy at all. The novel interpretations of these two new aspects are related to their historical sources, but both involve a slight “back-shifting” in time: *x-* indicates a recent event (similar to *ma*), but less recent: while being in within the same day as utterance time, it may not have happened *just now* (for instance, a few hours ago, or in the morning). Elkins (2023) and Scott (2023) both label this aspect ‘distal’ (DIST), to contrast with ‘proximate’ PROX. Similarly, $\emptyset$ indicates a past completive action (analogous to *o*), although slightly further back in time. That is to say, if a speaker is presented with two sentences, otherwise identical except for one having *o* and the other having $\emptyset$, the speaker will judge the latter event to have taken place before the former one. I gloss this aspect NCOM for ‘phonologically null completive’ moving forward.

		morpheme	meaning
(10) Todos Santos Mam aspectual system		<i>o</i>	completive
		$\emptyset$	null completive
		<i>ma</i>	proximate
		<i>x-</i>	distal
		<i>n-</i>	incompletive
		(<i>ok</i>)...-l	potential

Some examples of the innovative aspect morphemes are given below in (11-12). For the purposes of this paper, what's important to note about the phonologically null completive aspect is that it triggers the unusual agreement paradigm discussed in the introduction: Set B agreement is impossible, and the absolutive argument (in 12, an intransitive pronominal subject) may not be *pro*-dropped. As (11) shows, this appears to be a special property of the null completive aspect specifically, and not a property of the innovative aspect morphemes more generally in TSM.

- (11) Xhin jaw tz'aq *pro*
 DIST.B1S DIR fall
 'I fell (earlier today)' (x- + chin = xhin)
- (12) Ø (*chin) jaw tz'aq ***(qen)** / (**pro*)
 NCOM B1S DIR fall 1SG.PRON
 'I fell (yesterday or before)' (portmanteau morpheme *in* unavailable; cf. 8b)

3 The null completive construction

The empirical focus of this squib is the variation between two sentence types in TSM. Typically, Set B agreement faithfully cross-references absolutive arguments, which may be *pro*-dropped. In clauses with the null completive aspect, Set B agreement is impossible, and arguments may not be *pro*-dropped; instead, an overt pronoun must appear in argument position if the argument is pronominal, i.e. not a lexical DP. Example (1b) above shows this construction in an intransitive clause, however it is also observed in transitives (13c; 13a and 13b show default and faithful Set B, with overt aspect, respectively). Across both transitives and intransitives, Set B agreement and overt pronouns are in complementary distribution: Set B is associated with *pro*, and lack of Set B is associated with overt pronouns.³

- (13) Transitive clause with Ø NCOM
- a. Ma tz'-ok t-pju-'n Miguel ***(na'ya)** / (**pro*)
 PROX B2/3S-DIR A2/3S-hit-DS Miguel 1SG.OBJ.PRON
 'Miguel hit me' default Set B (informal)

³There are distinct sets of subject and object pronouns in TSM. Throughout this squib I only present 1SG examples: *qen* is used for intransitive subjects and *na'ya* ~ *na'yin* is used for transitive objects. See Elkins (2023) for more details.

- b. Ma **chin** ok t-pju-’n Miguel **(pro)* / (***na’ya**)
 PROX B1S DIR A2/3S-hit-DS Miguel 1 SG.OBJ.PRON
 ‘Miguel hit me’ “faithful” Set B (formal)
- c. $\emptyset$ {***chin**, ***tz-**} ok t-pju-’n Miguel (***na’ya**) / (**pro*)
 NCOM {B1S, B2/3S-} DIR A2/3S-hit-DIR Miguel 1 SG.OBJ.PRON
 ‘Miguel hit me’ null completive

4 Analysis

My analysis of the null completive construction in TSM rests on two key assumptions. I propose that we can understand the point of variation between clauses like (13a, 13b) and (13c) by making two assumptions with cross-linguistic support.

The first assumption I make is that the locus of Set B agreement is $T/Infl^0$ in high-ABS Mayan languages, not just Mam (Coon et al. 2014); this is also the head responsible for exponing aspect morphology. Coon et al. (2014) argue that the pre-verbal realization of Set B in high-ABS languages falls out from this high probe. They argue that the locus of Set B in low-ABS languages, on the other hand, is lower in the structure, namely on $v/Voice^0$. Evidence for this claim comes from the fact that in certain non-finite embedded clauses that lack aspect – and in which $T/Infl^0$ is by hypothesis absent from the structure – Set B agreement is impossible, or only available in a dedicated construction (such as the “crazy antipassive”; see Coon et al. 2014:221-225 for details). In low-ABS languages on the other hand, Set B agreement is straightforwardly possible in non-finite embeddings.⁴ The second assumption, following a suggestion by Armstrong (2017), is that $T/Infl^0$ in Mayan may host a Set B [$\mu\phi$] probe, or may lack such a probe.

With these assumptions in hand, consider again the critical alternation having to do with the null completive construction in TSM. In a clause like (13c), the phonologically null past completive aspect $\emptyset$ (NCOM) is used; I propose that this morpheme is the realization of a $T/Infl^0$ head that *lacks*

⁴The specific mechanism implicated in Mayan Set B agreement has long been taken to be clitic-doubling of the ABS argument (à la Kramer 2014). Coon et al. (2014) – which see for discussion – note that this has been defended for specific Mayan languages like Q’anjob’al (Grinevald and Peake 2012, Mateo Toledo 2008), Popti’ (a.k.a. Jakalteq; Woolford 2000), and Ch’ol (Coon 2013, 2017, Preminger 2011, 2014), as well as through historical evidence (Kaufman 1990, Robertson 1992).

a [$u\phi$] probe. Without this probe, $T/Infl^0$ does not enter into an Agree relation with the absolutive argument, and so Set B agreement never emerges. Regardless, I propose that, in transitive clauses featuring the null completive aspect, object raising still occurs. I schematize a transitive clause with the null completive in (14). I provide evidence for object raising and discuss it in more depth in §4.2.

This Agreement failure leads to an interpretation problem, since the absolutive argument can be *pro*. Without being able to express the ϕ -features of the pronominal argument by means of Set B, an overt pronoun must be pronounced in argument position.⁵ I therefore argue that pronominal forms in Mam are only licensed following successful Agree with $T/Infl^0$.⁶

How, then, are absolutive arguments in Mam licensed in the absence of Agree with $T/Infl^0$? I follow Scott (2023), who has previously proposed that the relevant arguments in Mam *are* successfully licensed, but that this licensing is not dependent on Agree with $T/Infl^0$. That is, Set B agreement and argument/case-licensing must be disentangled in Mam. Scott proposes that a lower head, namely $v/Voice^0$ Agrees with transitive objects; this head is also responsible (by being endowed with an [EPP] feature) for raising objects above subjects. Her proposal is that both the licensing of objects, and object-over-subject inversion, are separate operations from Set B agreement with $T/Infl^0$ (see Scott 2023, esp. pp. 142-157, for argumentation, which relies on object licensing in reduced matrix clauses in Mam). This claim has also been made explicitly for other high-ABS Mayan languages, such as for Kaqchikel by Ranero (2021). I return to additional diagnostics for disentangling object raising from Set B agreement in Mam in §4.2 below.

⁵This interpretation problem must be morphosyntactic, not pragmatic. If it were pragmatic, we would expect that if a discourse-salient pronoun were *pro*-dropped in a null completive clause, it could be recovered from context and the clause would thereby be grammatical; instead, the lack of an overt pronoun is entirely ungrammatical (see, e.g. 1b). I assume null *pro*-forms compete with overt ones in the morphological component of the grammar.

⁶This also helps explain why there are no overt ergative pronouns in Mam: ergative arguments are always successfully agreed with by the head that delivers Set A agreement, which is often taken to be $v/Voice^0$ in Mayan.

4.1 Against a purely phonological account

Here I consider an alternative analytical possibility: that Set B Agreement failure in TSM in the null completive construction is reducible to a phonological phenomenon (Woolford 2011). This approach takes its cue from a well-documented alternation in Tsotsil, a Tzeltalan-branch Mayan language unique in having both “high-series” and “low-series” Set B: Set B clitics are expressed pre-verbally just in case a phonological host is present (such as an overt aspect morpheme), or they must be otherwise phonologically optimized (15a); elsewhere, the clitics surface post-verbally, as in (15b) (Aissen 1987, Woolford 2011; see Coon et al. 2014:fn.8 for discussion):

(15) Variable Set B linearization in Tsotsil (Aissen 1987)

- | | |
|--|---|
| <p>a. Ch-a-s-mil
INC-B2S-A3S-kill
‘He is going to kill you’</p> | <p>b. J-mala-oj-oxuk
A1S-wait-PERF-B2P
‘I have waited for you (pl.)’</p> |
|--|---|

While this phonological account may be plausible for languages like Tsotsil, it does not appear to be extensible to Mam, for two reasons. The first reason was discussed above: other Mam dialects have null aspectual allomorphs that still appear to host Set B morphology. In Ixtahuacán Mam, the phonologically null dependent aspect morpheme ($\emptyset$ ‘COM_DEP’) – which I take to share a common source with TSM NCOM $\emptyset$ – is able to host Set B agreement, for instance with the portmanteau morepheme *in* (from $\emptyset$ + *chin*) for first singulars. Example (16), showing this state of affairs, repeats the sentence in (8b) above. I take this to imply that simply having a phonologically null aspect marker does not immediately lead to Set B agreement failure in Mam.

- (16) T-uj b’ee in jaw tz’aq=a
A2/3S-RN:in road COM_DEP.B1S DIR fall=1S
‘It was in the road that I slipped’ (England 1983:162)

The second reason is that pre-verbal Set B in TSM may appear *without* a phonological host or other phonological optimization; this is evidenced by control clauses like (17), in which there is no phonological material in the embedding to which the Set B morpheme could plausibly attach.

- (17) W-aj *pro*_i [**chin** jaw majee' PRO_i]
 A1S-want B1S DIR marry
 'I want to get married'

These two pieces of evidence point to the fact that TSM has innovated a special aspect morpheme that (i) is phonologically null, and (ii) lacks a Set B [$\mu\phi$] probe. The comparative data from Ixtahuacán Mam indicates that these two features are not inherently correlated.

4.2 Disentangling Set B agreement from object raising

I now consider two pieces of evidence in favor of the claim that we should disentangle object raising in transitive clauses from Set B agreement in high-ABS languages by looking more closely at the null completive construction in TSM. First, even within an null completive clause, ergative extraction is banned, indicating that object-over-subject inversion has still taken place (18a). An antipassive is likewise used to circumvent this ungrammaticality (18b).

- (18) a. *Al_i $\emptyset$ ok t-pju-'n *t_i* Miguel?
 who NCOM DIR A2/3S-hit-DS Miguel
 Cannot mean: 'Who hit Miguel?'
 b. Al $\emptyset$ ok pjuu-n t-e Miguel?
 who NCOM textscdir hit-AP A2/3S-RN:PAT Miguel
 'Who hit Miguel?'

The second piece of evidence comes from patterns of syntactic binding, first explored by Royer (2022, 2025). In Mam, possessors within $\bar{A}$ -moved objects may be R-expressions co-indexed with a pronoun, even in the aspectless construction (19a); at first glance, this is an apparent violation of Condition C of the Binding Theory (Reinhart 1976, Chomsky 1981). In (19b), we see that the ergative subject must not be realized as an R-expression (at least with these indices). This pattern has been shown to hold in other high-ABS languages, like Chuj, Q'anjob'al, and Kaqchikel, but low-ABS languages, like Ch'ol, show the reverse pattern of grammaticality (Royer 2022, 2025; see also Coon and Royer 2025).

- (19) a. [Ja t-waakxh [POSS **María_i**]] ∅ txi' t-k'a'y-in [SUBJ **pro_i**]
 DEM A2/3S-cow María NCOM DIR A2/3S-sell-DS
 Lit. 'It was *María*'s_i cow that she_i sold'
- b. *[Ja t-waakxh [POSS **pro_i**]] ∅ txi' t-k'a'y-in [SUBJ **María_i**]
 DEM A2/3S-cow NCOM DIR A2/3S-sell-DS María
 Cannot mean: 'It was *María*'s_i cow that she_i sold'
 (OK if the possessor has a distinct index)

Royer explains that the pattern in (19a) is not a true violation of the Binding Principles precisely because of the mechanics of object raising. When the object A-moves above the subject, its possessor is not in a position to c-command the subject, so it is entirely grammatical to realize an R-expression in object possessor position. Assuming that $\bar{A}$ -movement reconstructs for Condition C (Barss 1986, Heycock 1995, Fox 1999), when the object is then $\bar{A}$ -extracted (as in 19a), the R-expression is still free in its reconstructed position above the ergative subject.

The major takeaway from these two diagnostics, then, is that objects in TSM consistently undergo raising regardless of whether T/Infl⁰ will ultimately assign them Set B (14).

5 Conclusion

In sum, I have presented an analysis of the null completive construction in TSM to argue that that the variable patterns of absolutive case assignment in the language reflect whether T/Infl⁰ bears a Set B probe or not. I provide evidence that Set B agreement failure in the null completive construction cannot be reduced to a purely phonological mechanism (as in Tsotsil; Woolford 2011). I have also demonstrated that this construction gives us further evidence that objects consistently raise in high-ABS Mayan languages like Mam, regardless of whether they will eventually be Agreed with, and assigned Set B by, T/Infl⁰.

This discussion adds yet another piece to the already complex picture of variation among Mam dialects with respect to in Set B agreement and case-licensing (Elkins 2023, Scott 2023, Myers 2025). It may also provide a useful framework for understanding the variation in clause types involving unique flavors of T/Infl⁰ in other Mayan languages and beyond.

Abbreviations

A = Set A (ergative/possessive); AP = antipassive/intransitive suffix; B = Set B (absolutive); COM = completive; DIR = directional auxiliary; DS = directional/transitive suffix; INC = incompletive; OBJ = object; PAT = patientive; PERF = perfective; PL = plural; PRON = pronoun; PROX = proximate; RN = relational noun; SG = singular; 2/3 = second or third person

Acknowledgements

I would like to extend continued gratitude to Mam language consultant Wilmer Mendoza – *chjonte tey!* This project also benefited from fruitful discussion with Joshua Lieberstein, Willie Myers, Harold Torrence, and audiences at UCLA's American Indian Linguistics Seminar and the 50th meeting of the Penn Linguistics Society.
