

BAVARIAN COMPS – AS PLAIN AS SIMPLE

Hubert Haider

Univ. Salzburg, FB Linguistik & R&K Academy for Evidence-Based Grammar Research

Abstract: This is a squib on doubly-filled Comps and an exercise in dealing with a tight spot. Not everything that is rated acceptable is grammatical, and not everything that is rated unacceptable is ungrammatical. The variety of double-filled comps in Bavarian dialects provides a good example of this, and a fine complication, too. Its resolution is called “decision overload”.

1. What it is about

Thanks to work of Josef Bayer, Generative Grammar theory has taken note of remarkable things in some Bavarian dialects already in the 80ies. Seven of his articles published since then have just been released as an anthology on Bavarian syntax (Bayer 2025) and I happened to be invited to review it. (Haider 2026). In the aftermath, I would like to leave a few comments on “doubly-filled Comps” and “inflected Comps” in particular, and on “Bavarian” in general, and link this to a discussion on data analysis. I have come to the conclusion that it is easy to miss the mark when analysing a supposedly excluded pattern that is central to a theoretical assertion. Contrary to Josef’s repeatedly published analysis, it does not seem necessary to invent any auxiliary hypotheses with something named “latent C-features.”

First of all, a note on the term “Bavarian”: Contrary to what the title – “*Bavarian Syntax*” – seems to suggest, there is no Bavarian language. Bavarian is a multifaceted language group that is commonly referred to as Bavarian dialects, sometimes with a condescending undertone. Bayer’s anthology deals with the characteristics of a selection of data from western Middle-Bavarian dialects, which are syntactically remarkable, but not representative for the entire Bavarian dialect area. South-Bavarian dialects do *not* participate in all these grammatical activities, or only to a highly fragmented extent, as a contact phenomenon.¹ These dialects are spoken in their eastern extension in Carinthia, then in its western extension in parts of Salzburg, in South Tyrol (Südtirol), and in the northwest as far as North Tyrol (Nordtirol).

Due to their age, the author of the anthology and the author of this squib belong to the “last generation” of *monolingually reared* L1 speakers of a Middle-Bavarian dialect. We had the chance to acquire our dialects through monolingual language acquisition. At least since the fifties, more and more children grew up bilingually, with dialect and standard variety.² People started to commute to cities and back. As for me, I first came into contact with the standard language at the age of seven, when I started with the elementary school, where it was taught and imposed on me. At home then, there were no distractions by television or reading aloud before bedtime. The dialect remained my primary language until I moved out of my parents’ village inn at the age of nineteen.

¹ This information I gratefully acknowledge to Hannes Scheutz, who has been researching Southern-Bavarian and Middle-Bavarian dialects for decades as a field linguist. Southern Bavarian dialects, for example, do not use “inflected comps.”

² Already 10 years can make a difference, as I found out when I tested family members on dialectal causative constructions. My younger brother had no command of the dative assignment to the external argument of the infinitival verb anymore. He insisted on the standard version with accusative. See Haider (1989).

Presently, I find myself in a linguistically delicate situation in which Josef Bayer and I disagree on a central set of data. In fact, I am the conservative part, it seems, since for me, the data he presented as grammatical in 1984 are still grammatical and by and large also acceptable. He, however, apparently underwent a change of heart. Since about a decade, he has found part of what he used to previously accept as grammatically correct to be ungrammatical. What has changed? Was it the dialect or a refined command of the grammar of the dialect, or was it the seductive effect of an attractive theoretical hypothesis?

Ten years ago, when I grew aware of this change of mind, it prompted me to ask him by mail: Has the dialect changed in the past thirty years, or has it merely been the author's assessment of the data that changed? The prompt, friendly, and honest reply stated: *“I didn't know at the time that this didn't correspond to reality, and no one seemed to have noticed anything. Thankfully, this has changed as a result of the empirical turn.”* [J. Bayer, p.c., October 8, 2015].

Of course, no one is prohibited from becoming more experienced, but what about the scientific community and the “wisdom of the crowd”? As a native speaker, he had presented the data honestly, and since then, no one had raised any objections except for himself, a quarter of a century later. Either no linguist familiar with the subject has taken note of the content of the work, which we can safely rule out, or no linguist has found any reason to raise objections, which is more likely. I, on the other hand, had immediately taken offense at the *re*-rating. So, what is this all about?

2. The matter of dispute

Let us start with the uncontroversial part. In Middle-Bavarian *wh*-movement constructions, the specifier of *Comp* and its head position can be lexicalized at the same time. A very frequent pattern is one with *wh*-PPs, as in (1)

- (1) a. De Frau hod hiaz gwusst, [*fia* *wos* [*dass*‘ [oawadd]]]]³
 The woman has now known *for what that*’s(he) works
 b. (wea wo dahaam is und) [*wüa-fü* [*dass* [‘s oiso san]]]]⁴
 (who where at-home is and) *how-many that* they therefore are

We agree furthermore that in (2) – all examples are quoted from Bayer (1984), reprinted (2025: 17;77) – not every utterance sounds equally lifelike. We disagree, however, on the degree and the cause of the gradience. In later work of his (2025:137, 142, 170), the pattern (2a), that is “*wos dass*”, is considered ungrammatical and the examples are starred henceforth. In the figures on acceptability ratings, however, (2b) and (2c) proved to be closer to the evaluations of the patterns in (1) than to deviating statements.⁵

- (2) a. I woß ned *wos daß*-ma toaⁿ soⁱn
 I know not what that-we do should

³ [https://bar.wikipedia.org/wiki/De_Spinnarin_am_Kreiz_\(Wean\)](https://bar.wikipedia.org/wiki/De_Spinnarin_am_Kreiz_(Wean))

⁴ Wienerisch (Viennese): Teuschl. Da Jesus und seine Hawara.

⁵ Höhle (2018: 407) notes that “*wen dass*” is available also in standard German, if a Verum-Focus rests on “*dass*”: i. Jetzt möchte ich wissen, wen DAB du reingelegt hast.
 Now would-like I know, whom that you fooled have.

- b. I woäß ned *wer daß des tauⁿ hod*
 I know not who that this done has
- c. I woäß ned *waun daß da Xaver kummt*
I know not when that the Xaver comes

This is our little ‘casus belli’. According to Josef, (2a) is ungrammatical, as are (2b,c), although the latter receive more leniency in the acceptance assessment. In my view, the whole pattern in (2) is a grammatical pattern, but the acceptability is reduced by interference factors, and this leads to the rejection of (2a) by native informants.

So, the basic disagreement is the following: Do informants who report gradient judgements sense the offense of grammaticality or is it an unpleasantly increased processing effort that they experience? This is a dilemma that is notoriously difficult to resolve. Bayer (2025: 180) argues that it is a matter of grammar, I am the advocate of a processing-based account.

As a speaker of such a dialect, I can imagine how an informant confronted with (2a) is likely to feel and that the version without “dass” turns out as preferred. But my feelings and the feeling of any informant are cognitively encapsulated and inaccessible to introspection. The factors that contribute to the respective ratings remain unconscious and can be fed by virtually anything. Therefore, we obviously have no choice but to tackle these issues the difficult way, that is, to get to the bottom of them scientifically.⁶

3. *Wos* – a grammatical multitool

“*Wos*” has something special about it, but what is it? Is “*wos*” the outlier, or are there other wh-items like it? There are, as Bayer (2025:161) claims. His diagnosis is depicted in (3). Clause-initial wh-words in general, unlike wh-phrases, are ungrammatical in combination with the complementizer “*dass*”. Why this?

- (3) * $[_{CP} \text{ wh-word } [_{C'} \text{ dass}_{C^0} \dots]]$ Bayer (2025:161)

Here is Bayer & Brandner’s (2008) hypothesis, that Josef favours since then. Pronouns in general and wh-pronouns in particular, are first of all elements in which the form of a lexical X^0 category (= word level) does not differ from the form of a phrasal category.⁷ Secondly, they are deemed to be endowed with “a latent *C*-feature” (auxiliary hypothesis), and ultimately, an economy principle of grammar (auxiliary hypothesis) is at work that eliminates (3) as an instance of avoiding redundancy. The result is (4).

- (4) $[_{CP} [_{C'} \text{ wh-word } \dots]]$

Because of its “latent C^0 -feature” $[+C^0]$, a wh-word may serve as an X^0 -level complementizer, whence there is no grammatical license for an additional, regular complementizer. In (4), the question word occupies the complementizer position in which “*dass*” would be able to occur

⁶ In the 21st century, methods for finding this out could of course include (i) an ERP experiment with checks of the amplitude of N400/P600 when presenting “*wea dass*” compared to “*wos dass*,” or (ii) an eye-tracking reading experiment that examines the dwell time on “*dass*” as a function of the integration effort caused by the preceding words, namely *wos* vs. *wer*. If my analysis is correct, only “*wos dass*” triggers an N400/P600 signature, and the latency for “*dass*” is longer when preceded by ‘*wos*’ than when preceded by “*wer*” or “*wen*” or “*wo*”. I fear that our current discussion must remain somewhat retro due to the lack of the necessary technical equipment.

⁷ One could argue just as well that pronouns are lexical DPs, as in Haider (1992).

otherwise. It usurps its place, therefore (3) is deviant. Under this hypothesis, expressions of the structure (3) are not only of reduced acceptability, they are right away ungrammatical.

What is the price of this solution? Firstly, a hitherto unknown technical device, a “latent feature,” is introduced into the grammar-theory inventory as an ad-hoc measure. Secondly, this feature has to function as an entry ticket for a candidate who, being a principal phrase-equivalent element, would otherwise have no access to a C° position. Thirdly, there is an unknown but strict usher who pushes the *wh*-word into the C°-head position. In my opinion, that's quite a lot of grammatical effort for a little *Wh*-word. Therefore, equally strong, independent, and convincing evidence is required before one is prepared to accept this.

A first piece of evidence that appears to neatly fit Josef's analysis comes from my own eastern Central-Bavarian dialect. In relative clauses, we use ‘*wos*’ (what) instead of the western Middle-Bavarian ‘*wo*’ (where).⁸ *Wo/wos* is optional and, on the other hand, the relative pronoun is optional if its case matches the antecedent, but one of the two ingredients must be present.

- (5) a. *dea Breiss, dea (wo) gjodl hod* (Merkle 1975: 149)
 the Prussian who (*wo*) yodeled has
 b. *dea Breiss, dea (wos) gjodl hod* Eastern Middle-Bavarian
 the Prussian who (*what*) yodeled has
 c. *dea Breiss, wo/wos gjodl hod*

If *wo/wos* is bound to occupy the C°-position, this solves the problem with (5a,b), when both, the relative pronoun and the *wh*-element, are present. There is a single Spec but otherwise, there would be two competing candidates. The dilemma of relative clauses disappears once structure (6) is assigned to the examples (5a,b), but a new dilemma arises (6b).

- (6) a. ... [CP *dea* [C° *wos/wo* [...]]] Relative clause
 b. ... [CP *wo* [C° *wos* [...]]] *Interrogative clause with two *wh*-pronouns

If ‘*wos*’ may occupy the C°-position, this would open the structure (6b) as a structure of an embedded multiple-*wh* clause. But that would mean B&B would be fighting themselves at their own game. There can be no doubt that (6b) is the wrong structure for capturing the ‘inflection’ data.⁹ According to (6b), “*wos*” would have to be the target, but this is wrong. The target is “*wo*”. The reason is, that “*wo*” is *wh*-moved while “*wos*” is still in its base position.

Why would anyone find fault with Bayer & Brandner's (2008) neat solution, apart from (6b)? Well, it seems they are overgeneralizing the idiosyncrasy of *wos*, and Ockham's razor therefore strikes back mercilessly. “*Wos*” is the polar case, but classifying all other word-level *w*-elements as members of the same category in order to achieve the strongest possible solution goes too far. That's too much of a good thing. At this point, our opinions begin to diverge, in theory and even more so on empirical grounds (see below).

In my increasingly firm professional opinion, the key is a proper understanding of the grammatical role of “*wos*” since unlike other word-level *wh*-elements, this is a really multifunctional

⁸ Dialectal L1-speakers are known to import this pattern in their approximation of standard German:

i. ein Partner, der *was* das mitmacht (a partner, who *what* goes along with this)

⁹ i. koa Aunung, [CP *wo'st* [wos hinglegd hosd]] – no idea where what you put

ii. *koa Aunung [CP *wo* [wos't [hinglegd host]]]

Moreover, the position for an overt “*du*” (you) is right after “*wo*”, rather than after “*wos*”. “*Wos*” is not in C°.

grammatical device for a large family of constructions, with Comp serving as its site of action. Here is a list of the individual grammar 'jobs' in which "wos" is involved.

- | | |
|---|--------------------|
| (7) a. <i>Was</i> passierte? | interrogative |
| What happened | |
| b. <i>Was</i> er sagt gilt. Das ist alles, <i>was</i> er kann. | relative |
| What he says goes. That's all <i>what</i> he can do. | |
| c. <i>Was</i> meinst Du, <i>was</i> sie sagen, <i>wer</i> das herausgefunden hat? | wh-scope extension |
| <i>What</i> do you think <i>what</i> they say <i>who</i> discovered it? | |
| d. des gaunze Zeig, dees <i>wos</i> dea lesd | relative |
| the whole stuff this _{Rel-pr.} <i>what</i> this-one reads | |
| e. mea leid, ois <i>wos</i> ma glaum mechd | comparative |
| more people than <i>what</i> one think might | |
| f. Ea schreid so laud wos/wie'ra kau ^{n.10} | comparative |
| He screams as loud as <i>what/how</i> 'he can. | |
| g. (Sog ma gschwind) <i>wiaFÜ</i> (Euro) <i>wos</i> des ois kost | interrogative |
| tell me quickly <i>how-much</i> (Euro) <i>what</i> this all costs | |

Standard German (7a-c) does not partake in relative and comparative formation of the type (7d-g). All patterns in (7) occur in Middle Bavarian dialect varieties, if not in all of them. The last one is of particular interest. In (7g),¹¹ "wos" clearly is a C°-Element, otherwise it could not co-occur with a full wh-phrase.

What we see here is a fairly clear case of a functional item subserving a variety of Comp-related functions. The function as an interrogative pronoun is only a part of this portfolio. The majority of the other functions are functions of a functional lexical item without the reading of an interrogative operator and associated with the top-most functional *head* position of a clause.

4. It's not the grammar that's to blame, but processing is the problem

Now we are able to approach the "wos-dass"-intolerance enigma from a different angle, namely as triggered specifically by "wos". Here is what this means: Anyone confronted with instances of (2a) – viz "wos dass" – is caught in a *decision dilemma* when processing them. It is the opposite of a garden path effect (= no option available). Computation is difficult also in a situation with *too many* options. An extreme form of choice overload would even lead to decision paralysis (= no option can be selected due to the availability of too many possibilities).

In contexts (7d-g), a combination with "dass" is excluded, and there is no report of a finding to the contrary. The combination with "dass" is only appropriate in the function of a question operator, on a par with *who*, *whom*, *where*, or *how*, as in (8). So, what makes (8d) a special case?

- (8) a. *Wea dass* dees gsogt hod kundad I nimma sogn.
Who that this sid has could I not-anymore say

¹⁰ <https://afk-lembach.at/neustift/2012/06/26/da-oarme-feiawehrhauptmann/>

¹¹ As for (7g): None of the over-60-year-old speakers of my dialect whom I took advantage of at the hairdresser's today (Oct. 9th, 2025) chose "wiafÜ dass." I had asked them: How would people who grew up with our dialect ask this very question? "... wiafÜ dass ..." or "... wiafÜ wos ..."? They all preferred "wiafÜ wos". Me too.

- b. *Wia* dass dees gehd woas a koana.
how that this goes knows nobody
- c. *Wo* dass dees stehd woit's wissn.
where this written-is wanted-she know
- d.(?()) *Wos* dass dees den soi, hod a mi gfrogd.
what that this all (about) was, has he me asked.

In (8d), the combination of two individual elements, each of which is at least a potential candidate for the same position, is a *disambiguation* task, and it is aggravated since “*wos*” is a multi-purpose item, which activates many kinds of syntactic associations. The effect on a situation of decision making – the task of the informants – is known as cognitive dissonance.¹² The language user, who is under pressure to make a decision, avoids this situation and – – devalues the test item by avoiding it. This is why (8d) is not in use and subsequently starred or question-marked.

Whenever a pattern tends to be avoided, its corpus frequency is low. Nevertheless, there are specimen as (9a) and, what was a real surprise to me, the Bavarian grammar site of the Bavarian version of Wikipedia explicitly lists (9b) as an example. Who could seriously object? Let Bavarians do what Bavarians do.

- (9) a. Woaßt, *wos* dass da durche Dier eini kimmd¹³
knows-you, what that there through-the door in-comes
- b. Woaßt, *wos* dass des ois bedaet?¹⁴
knows-you, what that all means
- c. [Za *wos*]_{PP} dass dees guad sei soi, woass a koana.
for what that this (to) be good should, knows also no-one

In contrast to the cognitive overload that (9a) and (9b) can cause in an unprepared listener, (9c) is an easily digestible dish. “*Wos*” is enclosed in the PP, and the juxtaposition in the word sequence is irrelevant for the parser, which is guided by the structure. Only within the same structure – specifier and head, or head and complement – does the parser encounter uncomfortable stress, and so does an informant.

Let us return to the master of Occam. “Non sunt multiplicanda entia praeter necessitatem” is the most venerable maxim I encountered in the philosophy of science, and not so much because of its age of about 700 years. No scientist can deny it, even if linguists do so by submitting to the Minimalist Program. There is no ontology for all kinds of abstract features, let alone latent features, and no need to lump all word-level wh-expressions together. The apparent oddball is “*wos*,” and we are able to figure out why.

5. That's not quite the end yet

The approach based on (4) – $wos_{wh[+C^\circ]} = C^\circ$ – has unfortunately caused further collateral damage. Here is an example of the data affected by it. The area of interest is the so-called inflected-Comp phenomenon, as illustrated in (10a). The term ‘inflected’ is inaccurate in this respect, as complementisers are a class of words that do not inflect, but merely exhibit morphological

¹² Cognitive dissonance is the psychological discomfort a person feels when confronted with conflicting information. To alleviate the mental tension, individuals tend to dismiss the conflicting information.

¹³ Northern Bavarian: https://www.reddit.com/r/ich_iel/comments/4xnrk4/ich_iel/

¹⁴ Specific example in the Bavarian Wikipedia: [https://bar.wikipedia.org/wiki/Boarische_Grammatik_\(Pronomen\)](https://bar.wikipedia.org/wiki/Boarische_Grammatik_(Pronomen))

markers for the *second* person, together with optional pro-drop. Whether this is an exceptional case of inflection or a result of cliticisation of the second-person pronoun, plus optional clitic-doubling, is still an open question.

- (10) a. I sog da, dass't/ob'st/wenn'st (du) mid eam redn kaunst.
 I tell you that_{+2nd}/whether_{+2nd}/if_{+2nd} (you) with him talk can
 b. I sag da, wo'st/ wia'st/wann'st/wos't (du) mid eam redn kaunst.
 I tell you where_{+2nd}/how_{+2nd}/when_{+2nd}/what_{+2nd} (you) with him talk can

Those who regard (10a) as an example of inflected complements are inclined to assume the same grammatical cause in (10b), where wh-pronouns display the same marking. After all, this leads to an attractive generalisation that no syntactician would want to miss out on: C° is a place for inflection, be it for the finite verb in V1 or V2 sentences, for a complementiser or for a W-pronoun, if it is in the C° position. If true, this is another solid piece of evidence for wh-pronouns as C°-items, that is, for the structure (4). Wh-pronouns would be ‘inflected’, but wh-phrases wouldn’t. What are the facts? Here we are now at the second point of contention. We, that is Josef and I, agree on the consequence but we disagree on the facts. The consequence is obvious. If wh-pronouns are only inflected in the C-position, wh-phrases cannot be inflected. Here is the pertinent declaration: „*Comp-inflection on wh-phrases is dispreferred or downright ungrammatical*“. Bayer (2025: 177).

- (11) a. *I woäß schoo, wos fia schuachst (du) ooⁿzogn hosd Bayer (2025:178, 156)
 b. *I woas schoo, wia oft's (ees) gfait hobts Bayer (2025:178)

The examples in (11) are starred as ungrammatical because of the following observation which is the summary of an elicitation experiment with nine speakers and ten test items: „*The results could not be clearer: There was not a single case of 2nd person inflection on an XP of the type was-für-DP or wie(viel)-XP.*“ Bayer (2025: 179).

To claim that the forms that appear with ‘inflected’ Comps cannot be joined with *phrases* would be an empirically inappropriate generalisation. Impartial grammarians such as Merkle (1975: 128. §25-27) and Nübling (1992:118-125) may be called as witnesses:

- (12) a. [je mehra]'sd (du) hosd
 the more (you) have
 b. [so guad und scheiⁿ]'sd as (du) a mo'sd
 as well and beautifully it you even paint
 c. [Wia bledda]'sd (du) frogasd, wia gscheidde warad's.
 how more-foolishly (you) ask, the wiser would-be'it
 d. [Wie me^a]'st (du) do noodengst, auf [wia mea]'st (du) do draufkimsst.
 how more (you) about-it think, about how more (you) find out
 e. Do hob I mea Sochan gfunden [PP ois-p° [CP (wos)'d [(du) dia voastön kaunsd]]]
 there have I more things found than (what)_{+2nd-p}. (you) yourself imagine can

Incidentally, the data in (12) are also representative of the reviewer's L1 dialect. What is striking about these data is that they belong to a construction that is completely absent from the anthology (with the exception of (11b) as an uncommented example), even though this construction in particular should not be missing, namely comparative and equative clauses (with “than” or “as”). Comparative clauses are well-renowned members of the wh-movement family. In (12a-

d), the 2nd-person-marking is definitively linked to a *phrasal* expression that is definitively not in a C°-position.

The last example, viz. (12e), is particularly intriguing. In dialectal comparative clauses like (12e), there occurs an optional wh-item, namely “wos” (what). In the absence of “wos”, the person marking is attached to the *preposition* “ois” (than): “ois’d”, which is not in a Comp position either. For details, please consult Haider (2010: 102-104).

Bayers’ attempt to disqualify (11) also highlights the crux of the matter with regard to elicitation data, which the author intends to turn into a strong argument: „*The results could not be clearer: There was not a single case of 2nd person inflection on an XP of the type was-für-DP or wie(viel)-XP.*“ Bayer (2025:179). The point is rhetorically boastful, but in terms of a valid argument, more than extremely weak: “Absence of evidence is not evidence of absence.” It should go without saying that this is a maxim a scientist cannot neglect.

Let’s recapitulate: Merkle (1975:128) and others are right. The person markings are not exclusively confined to Comp inmates and (11a,b) are grammatically well-mannered utterances. For duly thorough skeptics, here are a few more specimens of this variety, noted by Merkle (1975:127-128), who, by the way, is listed in the bibliography of the anthology. The appendix lists a few more, real-life finds.

- (13) a. Du soist ma sogn, [an wächan (schuach)]’sd wuisd
 You should me tell [a which (shoe)] want
 b. [wia hoch]’sd naufsteigsd
 how high (you) up-climbs
 c. [Wia gschlaumbbad]’ds ees daherkembds!
 how scruffy you_{pl.} come-along

This data not only refutes C° as the exclusive spelling-out position of the ominous second-person markers. This data is also evidence that cliticisation is the source of the second-person marker at the beginning of the sentence. A phrase cannot be inflected, only its head.

6. That’s the end of it

- Comps are not *inflected*. As clause-initial elements, they are targets of *cliticisation*
- Clitics may also target the very end of *clause-initial phrases*.
- When functioning as a C° element, ‘wos’ (what) occurs in relative and comparative clauses, but not as a question word in interrogative clauses. In such clauses, it is placed in the spec position.
- ??[wos dass ...]: This is an avoidance effect due to a decision dilemma (cognitive overload)
- There is no convincing grammatical justification for assuming a “latent C feature”.
