

(Everyone) **Everywhere** All at Once:

A relational account of quantified impersonal *-where* in English

Benjamin L. Sluckin

Ruhr-Universität Bochum

benjamin.lowellsluckin@rub.de

Abstract

On the surface, English [$Q+where$] forms such as *everywhere* are locative. Yet as [Sluckin and Kastner \(2026\)](#) document experimentally, they can also serve as impersonal human subjects, as in *Everywhere in the UK loves Marmite*, in which *everywhere* = *everyone*. Notably, the form retains its locative morphology and the pro-form *where*, yet it binds *they/their* and controls like a [+HUMAN] quantified indefinite pronoun. It must also be distinguished from ordinary locative (every place) and metonymic institutional readings. We argue that the impersonal use emerges from a distinct syntactic configuration in the nominal domain, rather than from lexical polysemy. *Where* spells out a higher locative D/P shell, while beneath it sits a silent, sortal, human-descriptive root $\sqrt{\text{PERSON}}$, selected by a relational categorising head n^{CAT} bearing [uPlace]. Relationality comes from the categoriser, not from the root (cf. [Adger 2013](#)). The [uPlace] feature forces an overt macro-geographic PP into $\text{Spec}, n\text{P}^{\text{CAT}}$, where it saturates the place argument of an inhabitant relation; n^{EA} then abstracts over the human variable, and the quantifier binds the resulting property. Because the root is silenced by local zero exponence under this categoriser, rather than by the higher shell, its human content remains active though unpronounced. Institutional *everywhere*, by contrast, retains a $\sqrt{\text{PLACE}}$ structure with contextual transfer. The obligatory locative PP follows from [uPlace], whereas the macro-geographic restriction is an interface condition rather than a syntactic feature.

keywords: quantifiers, impersonal pronouns, locatives, indefinites, metonymy, silent nouns

1 Introduction

1.1 The phenomenon

English [$Q+where$] expressions do not uniformly quantify over places. The same surface family supports at least three referential domains: ordinary locations, place-linked institutions, and,

in a restricted impersonal construction, human inhabitants of a locative domain. The central question of this paper is how one *where*-based paradigm can support these place-, institution-, and person-oriented readings without reducing them to simple lexical polysemy.

The baseline use is locative. In (1), *everywhere* ranges over places.

- (1) I've looked *everywhere* (in this house) for the keys. **locative**

A second use is institutional. In (2), *everywhere* can quantify over shops, businesses, or other institutions associated with the relevant locations.

- (2) *Everywhere* (in the UK) takes credit cards these days. **institutional**

A third use is impersonal. In English, a restricted *everywhere* has been shown to be capable of denoting an impersonal subject referring to a generic set of people/inhabitants in a given geographic location, as in (3) (cf. [Sluckin and Kastner 2026](#)). The apparent-time study by [Sluckin and Kastner \(2026\)](#) demonstrates that a growing number of English speakers accept the construction; it is primarily anchored in British English, though it can be found to a lesser extent in North American varieties and beyond.

- (3) a. *Everywhere* in the UK eats fish and chips.
b. *Everywhere* on the coast eats fish and chips.

The canonical and clearest impersonal use is tied to an overt locative PP. Without an appropriate locative domain, the impersonal reading is unavailable or sharply degraded; moreover, the domain must be geographically large rather than narrowly local.

- (4) *Everywhere* (#in the village)|??(in the UK) eats fish and chips.

1.2 The puzzle

The three-way typology is the framing problem for the paper: one surface family quantifies over places, place-linked institutions, and human inhabitants without collapsing these readings into unconstrained lexical polysemy. Within that broader frame, four more specific puzzles drive the analysis.

- (1) *Obligatoriness of the PP*. Why is the PP-restrictor required in the canonical impersonal reading and optional for the institutional reading, when both involve the same surface form [*every+where*]?
- (2) *Restrictor size*. Why is the PP additionally constrained to denote a large geographical domain (*in Italy* but not *in Italian restaurants*)?
- (3) *The DP-locative tension*. The construction binds, controls, and antecedes pronouns like a full DP, yet its head exponent *where* is a locative pro-form. How does a locative element license full DP-licensed A-positions?

- (4) *The split with everyone.* *Everywhere* replaces *everyone* in precisely those contexts where a covert human argument has been claimed to be independently available and licensed by a PP (see Brody 2013), suggesting a non-accidental relation to existing mechanisms for impersonal licensing in English. What is that relation?

1.3 The proposal and roadmap

The proposal of this paper combines three independently motivated assumptions: the Kaynian silent-noun architecture for locative pro-forms (Kayne 2005); a layered extended nominal projection composed of two functionally distinct nP layers [nP^{EA} [nP^{CAT}]] (see Roberts 2019) under a P-headed extended projection (Grimshaw 2005); and the observation by Brody (2013) that English locative PPs license a covert generic PEOPLE argument. The broader claim is that the three readings are structurally differentiated. Locative [$Q+where$] is built over a silent $\sqrt{PLACE}$ root. Institutional [$Q+where$] retains this locative structure but receives a contextual institution-oriented interpretation. The impersonal reading is the most complex case: it has the same external *where*-morphology, but its lower nominal domain contains a silent human root.

Proposal: The impersonal use of *everywhere* is the spell-out of an extended nominal projection with three defining properties:

LEXICAL	The unpronounced root is the silent sortal, human-descriptive $\sqrt{PERSON}$, in contrast to the silent sortal locative $\sqrt{PLACE}$ of the locative use.
CATEGORISATION	$\sqrt{PERSON}$ is selected by a <i>relational</i> categoriser, n^{CAT} .
SELECTION	The locative PP merges in $Spec, nP^{CAT}$, driven by a c-selectional [uPlace] feature on the relational categoriser n^{CAT} .

The lexical and structural properties are interdependent. $\sqrt{PERSON}$ is itself sortal — denoting the descriptive content of being a person — but its embedding under a relational n^{CAT} yields a 2-place inhabitant relation. The relational structure is contributed by the categoriser; the root contributes only human-descriptive content. In the canonical overt-PP construction analysed here, the [uPlace] feature on n^{CAT} is valued by the locative PP, which supplies the spatial argument of the inhabitant relation.

The higher categoriser n^{EA} abstracts over an individual variable (λx) interpreted as a human referent. The resulting human property serves as the restrictor for the universal Q^0 head (*every*).

This structure, as we will show, captures the empirical properties of the construction, including the split between institutional and impersonal generic interpretations.

Although we focus on English throughout, the crosslinguistic typology of impersonal pronouns is well-studied (e.g. Cinque 1988; Egerland 2003; D’Alessandro 2007; Alexiadou and Carvalho 2017). To our knowledge, no exact analogue has yet been described in the languages most often discussed in that literature, such as German *man*, Italian *si*, and French *on*. Indeed,

brief exploration of consultant judgements indicates that the English pattern is ruled out in major continental Romance and Germanic languages (5); systematic cross-linguistic comparison is left for future work.

- (5) a. Everywhere on the coast eats fish and chips.
 b. *Überall an der Küste isst *(man) Fischbrötchen.*
 everywhere on the coast eats IMP.PN fish-buns
 ‘Everywhere on the coast, one eats fish buns.’ **German**
 c. *Overalt i Norge spiser *(man) fårikål.*
 everywhere in Norway eats IMP.PN fårikål
 ‘Everywhere in Norway, one eats mutton and cabbage.’ **Norwegian**
 d. *Ovunque in Italia *(si) mangia la pizza.*
 everywhere in Italy IMP.PN eats the pizza
 ‘Everywhere in Italy, one eats pizza.’ **Italian**
 e. *Partout en France *(on) mange du steak.*
 everywhere in France IMP.PN eats of.the steak
 ‘Everywhere in France, one eats steak.’ **French**

Whether the structural ingredients we propose for English, i.e. a silent $\sqrt{\text{PERSON}}$ root under a relational categorising head with [uPlace], are available cross-linguistically remains open.

The paper proceeds as follows. Section 2 maps the three readings; Sections 3 and 4 develop the locative and institutional backgrounds; Section 5 gives the impersonal derivation; Section 6 turns to consequences and open questions; and Section 7 concludes the paper.

2 The empirical phenomenon

2.1 The experimental baseline

As introduced, the impersonal interpretation of *everywhere* has been documented in depth by Sluckin and Kastner (2026), who conducted an acceptability judgement study which tested 407 native English speakers (339 UK; 68 North American) on a 7-point Likert scale. The authors evaluated the construction across syntactic contexts which aimed to test the nature of the *everywhere* complex according to typical tests of argumenthood, subjecthood, and the thematic nature of the construction, e.g., binding, control, agent-oriented adverbs, object vs subject behaviour, and compatibility with different types of transitivity and voice alternations (see e.g., Williams 1987, 2015; Koenig and Mauner 2000; Roeper 1987; Landau 2010a; Bhatt and Pancheva 2006, 2017).

Ordinal Bayesian regression confirmed that the impersonal reading strictly requires an overt

locative restrictor (see 2.4). Bare *everywhere* was severely degraded across all demographics. Adding a PP restrictor denoting a very large location, which we label macro-geographic, rescues the construction by licensing full-DP syntactic behaviour of the entire *everywhere* complex, e.g., control via PRO and third-person plural binding (see §§2.5–2.6).

Sluckin and Kastner’s data also reveal regional variation; North American speakers rated the construction significantly lower than British speakers. The UK sample exhibits an age gradient: speakers aged 18 to 49 rate the restricted construction significantly higher than older cohorts. However, the fact that younger speakers reject the unrestricted bare form means that the phenomenon cannot be dismissed as broad pragmatic tolerance for colloquial metonymy. Given the apparent-time design of the study, Sluckin and Kastner (2026) conclude that the construction could well be an incoming structural change in the grammar of British English. While the diachronic implications of their findings warrant full formal explanation, the present study restricts itself to a synchronic analysis of the novel impersonal *everywhere* construction.

2.2 Three readings of [*Q+where*]

Everywhere in British English illustrates the three-way contrast introduced above. In its locative use, the quantifier ranges over places. In the *institutional* use, documented experimentally by Sluckin and Kastner (2026), it ranges over a set of institutions (shops, councils, universities) linked to places. In the *impersonal* use, it ranges over the human inhabitants of a geographic location and antecedes *they/their*.

- | | | | |
|-----|----|--|----------------------|
| (6) | a. | I’ve looked <i>everywhere</i> (in this house) for the keys. | locative |
| | b. | <i>Everywhere</i> (in the UK) accepts credit cards these days. | institutional |
| | c. | <i>Everywhere</i> *(in the UK) loves Marmite. | impersonal |

Table 1 summarises the three readings; the root and structural rows preview the analysis developed in §§3–5.

Table 1: Three readings of $[Q+where]$.

	Locative	Institutional	Impersonal
Root/semantic base	$\sqrt{\text{PLACE}}$	$\sqrt{\text{PLACE}}$ plus contextual transfer	$\sqrt{\text{PERSON}}$ under relational n^{CAT}
Referential domain	places	place-linked institutions	human inhabitants
Pronoun behaviour	locative <i>there/it</i>	<i>its</i> or <i>their</i>	<i>they/their/themselves</i>
Locative domain	optional PP adjunct	optional PP helps identify the institutional set	canonical overt macro-geographic PP saturates the place argument
Status of reading	structurally locative	contextual/metonymic	structurally encoded in the lower nominal projection

The impersonal reading, akin to *everyone*, falls within the quasi-universal range of the impersonal-pronoun typologies of Cinque (1988) and Egerland (2003), alongside English *one*, German *man*, Italian *si*, and French *on*. The remainder of this section sets out the properties that distinguish it from the institutional reading and from canonical locative *everywhere*.

2.3 The universal impersonal pronoun: *everyone*

Everyone represents the ordinary human baseline: a quantificational head combines with a human-denoting nominal restrictor. The relevant point for the present paper is not a full decomposition of *everyone*, but the fact that the human component is morphosyntactically accessible. This is visible in the contrast between (7a) and (7b): ordinary *everyone* supports *who*-relatives and human pronominal binding without further machinery.

- (7) a. Everyone who knows Mary loves her.
 b. **Everywhere* who knows Mary loves her.

Impersonal *everywhere* is thus exceptional. It patterns semantically with human quantifiers in binding and antecedence, but its external morphosyntax remains locative. The analysis below therefore asks how a human restrictor can be compositionally available inside a *where*-based form without making the expression morphologically identical to *everyone*. This contrast returns in the relative-clause diagnostics in §6.3.

For the time being, we assume *everyone* to be a case of ordinary universal quantification over a human-denoting pronominal nominal restrictor. In semantic terms, *every* combines with a property-type restrictor and yields universal quantification (see Heim and Kratzer 1998). Syntactically speaking, this can be schematically represented as a high QP ranging over a lower

DP human/pronominal nominal projection; this is in line with i) QP approaches to quantifiers (Shlonsky 1991; Matthewson 2001) and ii) analyses of pronouns as internally structured nominal/D-domain expressions (Postal 1966; Déchaine and Wiltschko 2002). Nothing in the present argument depends on the exact decomposition of *one*; the relevant point is that *every-one* supplies a morphosyntactically accessible human restrictor.

2.4 The restrictor

The central impersonal reading is licensed by an overt locative PP, and the PP must denote a large geographic domain. Removing the PP from a sentence that supports the impersonal reading collapses it onto the institutional reading (8); replacing it with a small or non-geographic PP degrades the impersonal reading even where the construction is otherwise well-formed (9).

- (8) a. **Impersonal/Institutional:**
Everywhere in England disapproves of public displays of affection.
- b. ***impersonal; institutional only:**
Everywhere disapproves of public displays of affection.

- (9) a. *Everywhere* in Italy likes to take a nap in the afternoon.
- b. # *Everywhere* in Italian restaurants likes to take a nap.

The size restriction is specific to impersonal *everywhere*. The locative-licensed (pseudo-)impersonal use of *they* described by Brody (2013) tolerates non-geographic restrictors when the predicate fits the location:

- (10) a. In Italy they like to take a nap in the afternoon. (ex. 4, Brody 2013:34)
- b. In Italian restaurants they make pasta properly. (ex. 16b, Sluckin and Kastner 2026)

A conceptual analogue is independently attested. Locations metonymically denote their human inhabitants only when the location can host a subdivisible population (PLACE FOR INHABITANTS metonymy; Radden and Kövecses 1999; Littlemore 2017), as in (11).

- (11) a. London drinks more than Edinburgh.
- b. # The living room drinks more than the kitchen.

Impersonal *everywhere* uses this option but imposes explicit structural restrictions on it: *in Italian restaurants* can support the metonymy but cannot license impersonal *everywhere*. §5.4 returns to this contrast, deriving PP-dependence from [uPlace] on a relational categorising head and treating size as an interface condition on the inhabitant relation.

The construction is also marginally available with a *that*-relative in place of the PP (12); Sluckin and Kastner (2026) report, in contrast, that *who*-relatives are generally ungrammatical. Relative-clause restrictors are discussed in §6.3.

- (12) Somewhere that believes they deserve her. (Sluckin and Kastner 2026)

2.5 Nominal status and human binding

Impersonal *everywhere* passes the standard diagnostics for full-DP-hood, applied in Sluckin and Kastner (2026) drawing on the implicit-argument literature.¹ It controls (13a), antecedes pronouns across clauses (13b), and binds reflexives, reciprocals, and bound pronouns (13c)–(13e).

- (13) a. *Everywhere* in the UK has been trying [PRO to quit smoking].
 b. *Everywhere* in the UK is saying it these days. They don't think it's strange.
 c. *Everywhere* in modern Britain helps themselves first.
 d. *Everywhere* in the country helps each other.
 e. *Everywhere* in England washes their salad before eating it.

(All examples from Sluckin and Kastner 2026)

Sluckin and Kastner (2026) present experimental data and a detailed discussion showing that the impersonal reading of *everywhere* targets a generic-human variable. This is evident in the fact that the bound pronoun of the impersonal use must be *they/their* or *themselves*; *its* is excluded on the impersonal reading. However, *its* is felicitous under the institutional reading, as shown in (14).

- (14) a. # *Everywhere* in the UK washes its salad before eating it. **impersonal**
 b. *Everywhere* (in the UK) sets its own council tax policy. **institutional, *its* licit**

The *they/their*-only pattern aligns impersonal *everywhere* with other indefinite human quantifiers, paradigmatically *everyone*, where singular *they* resolves a human-denoting variable bound by the quantifier (cf. Huddleston and Pullum 2002). The institutional reading admits both *its* and *their*, selecting between them on the basis of singular/plural construal of the metonymic referent.

2.6 Distribution

Two further properties constrain the analysis. First, impersonal *everywhere* is restricted to subject position; object positions force a locative or institutional reading.

1. For the diagnostic logic, Sluckin and Kastner (2026) cite Koenig and Mauner (2000) on pronominal antecedence, Williams (1987), Landau (2010a), and Bhatt and Pancheva (2017) on anaphor binding by implicit arguments.

- (15) a. *Everywhere* in the UK loves Marmite. **impersonal subject**
 b. # We visited *everywhere* in the UK. ***impersonal; locative only**

Second, the construction extends across the quantificational paradigm, with quantifier-specific rating profiles in [Sluckin and Kastner \(2026\)](#).

- (16) a. Somewhere in the world probably eats cat.
 b. Nowhere in the UK likes Andrew.
 c. I wonder if anywhere in the Middle East eats eagles.

The same impersonal structure must therefore be available below *some-*, *no-*, and *any-* as well as *every-*. §5 locates that structure inside the nominal projection, with the quantificational determiner merging above it.

Two questions follow from the observations in this section: what introduces the human variable inside a locative-looking QP, and why does the overt locative domain appear with it? The size restriction in (9) suggests that this domain must be able to support a subdivisible inhabitant population, while the extension across *some-*, *no-*, and *any-* shows that the effect is tied to *where*, not to *every* alone. In Sections 3–4, we develop the locative and institutional background. The syntax and semantics of the human variable and locative-domain requirement inside the nominal projection are set out in Section 5.

3 Locative *everywhere*: a layered nP analysis inside the extended nominal projection

To formalise the internal configuration of indefinite locative pronouns (e.g., *everywhere*, *somewhere*), we adopt the basic premise of [Kayne \(2005\)](#) that r-pronouns contain a structurally active, phonologically null spatial root that introduces a PLACE, his N_{PLACE} ; however, we motivate here an approach making use of a layered nP analysis (see [Roberts 2019](#)) and a P-headed extended nominal projection following [Grimshaw \(2005\)](#). This builds on [Kayne \(2005\)](#), but does not implement his exact proposals.

3.1 *where* as an indeterminate/indefinite pronoun

[Kayne \(2005\)](#) notes that non-standard English dialects show patterns involving r-pronouns like *here* and *there* which systematically co-occur with overt demonstratives, e.g., *this here book*. Consequently, he considers r-pronouns to function as determiner-like elements embedded within a larger DP-NP structure and proposes a syntactic configuration in which an unpronounced demonstrative determiner, akin to *that*, selects an NP housing the r-pronoun and the covert locative noun PLACE. To derive the surface order, the constituent containing the r-pronoun and

the covert locative noun undergoes leftward movement over the covert determiner (see [Kayne 2005:69–74](#)), as formalised in (17):

- (17) $[there\ PLACE]_i\ THAT\ t_i$ (ex. 30, [Kayne 2005:69](#))

While we accept Kayne’s premise of a silent *PLACE* root, an embedded phrasal movement derivation for *where* is less straightforward than the one he establishes for *here* and *there*. The empirical distribution of *where* diverges. First, *where* prohibits co-occurrence with overt determiners in prenominal position (e.g., **what/which where place*). While the ungrammaticality of an overt definite demonstrative (**that where place*) could theoretically be ruled out by a simple definiteness mismatch regardless of the D- or N-status of *where*, substituting the indefinite use of the demonstrative *this* ([Prince 1981](#)) yields the same crash: **this where place*.

While the prenominal sequence **what where place* is severely degraded, the postnominal sequence *what place where* is acceptable. In this configuration, *where* is an independent locative adjunct interrogating the established DP/NP complex, rather than a fundamental part of its internal architecture. This asymmetry indicates that *where* occupies a saturated maximal projection, incapable of acting as a modifier or determiner within the nominal spine.

To capture this distributional asymmetry, we model *where* not as a simplex D-head, but as a compositional P+D element derived within the P-headed extended nominal projection ([Grimshaw 2005](#)). The exponence of *where* is the result of a compositional derivation across the DP and PP layers.

First, treating *wh-* as an indeterminate/indefinite variable (cf. [Kratzer and Shimoyama 2002](#)), the *wh-* feature merges into D^0 , selecting an nP as its complement. We expand on the exact internal architecture of this nP in the next section, but for now, we assume equivalence to Kayne’s silent N_{PLACE} in order not to overburden the current argumentation. This aligns with the standard generative consensus that pronouns intrinsically occupy the D-layer and select an unpronounced nominal complement ([Postal 1966](#); [Abney 1987](#); [Panagiotidis 2002](#)). Any attempt to merge an external determiner over the projection triggers a structural violation, since D^0 is lexicalised via *wh-*. This accounts for the ungrammaticality of determiner stacking (e.g., **this where place*).

We assume that the P^0 head is the locus of the locative *-ere* morphology. Once P^0 merges above the DP, the D^0 element *wh-* incorporates into P^0 (see [Baker 1988](#)) via head movement. This incorporation is a narrow-syntactic operation rather than a purely post-syntactic or PF displacement (cf. [Matushansky 2006](#)). Incorporation via head movement thereby yields the morphological portmanteau *where*. Simplified versions of the “base”-generation and spell-out derivation are given in (18a,b); these are schematic, and we expand the nominal layer in §3.2.

(18) a.

b.

Thus, the silent nominal root inside the complement of D^0 is not itself pronounced by this operation; the overt form *where* realises the complex incorporated D/P unit.

3.2 Variable Introduction by n – A VoiceP–nP parallel

We formalise the internal configuration of the locative pro-form *where* by adopting a split nP architecture (Roberts 2019). We follow Roberts (2019) in separating two functions that are often bundled together in the nominal domain. The lower categorising head n^{CAT} merges with the root and determines the nominal category of the expression. This assumes that acategorical roots require syntactic merger with categorising functional heads (Embick 2015; Embick and Marantz 2008). The higher head n^{EA} introduces the nominal referential argument, the R-role (Williams 1981), by abstracting over an individual variable. This division parallels the separation between verbal categorisation and argument introduction in the clausal domain: categorisation is handled low, while the variable made available for binding by higher functional structure is introduced at the edge of the nominal phase.

We motivate the semantic mechanics of n^{EA} via a structural parallel between the clausal Voice domain and the nominal n domain. Following Schäfer (2008) and Alexiadou et al. (2015), we take the introduction of an argument role to be separable from the syntactic projection of a specifier. Active Voice introduces an external-argument role and bears an edge feature that projects a specifier hosting the external argument; non-active Voice introduces the role but lacks the edge feature, leaving the argument unsaturated in narrow syntax and bound from above by existential closure in the passive case (Bruening 2013; Alexiadou et al. 2015).

We propose that n^{EA} in the locative pro-form *where* is the nominal counterpart of non-active Voice. The lower categoriser n^{CAT} merges with the root $\sqrt{\text{PLACE}}$ to provide its nominal status, i.e. Kayne’s N_{PLACE} , and n^{PCAT} denotes a property of locations, $\lambda y.\text{PLACE}(y)$, of type $\langle e, t \rangle$. Immediately above this, n^{EA} identifies the open variable in its complement n^{PCAT} as the R-role

of the nominal projection (Williams 1981; Roberts 2019).

Whether this variable is syntactically saturated by a DP merging in $\text{Spec}, nP^{\text{EA}}$ is controlled by an independent edge feature on n^{EA} . In the locative pro-form, n^{EA} lacks this edge feature; no specifier is projected and no DP saturates the variable via Functional Application. The R-role variable remains open at nP^{EA} (still type $\langle e, t \rangle$) and is bound from above by a c-commanding operator.

(19)

If the locative pro-form were to resolve as a referential pronoun (type e), it would clash with quantificational heads like *every*, which require a property-type restrictor (type $\langle e, t \rangle$) as their first argument (Heim and Kratzer 1998). Because n^{EA} inherits the open property of its complement without saturating the R-role, nP^{EA} remains a 1-place property of locations. Following the standard treatment of indefinites as introducing free variables (Kamp 1981; Heim 1982), the *wh*-feature on D^0 takes nP^{EA} as its restrictor without supplying quantificational force; the resulting DP denotes an open expression of type $\langle e, t \rangle$.² The free variable is bound by a c-commanding operator higher in the extended projection, e.g., the universal quantifier *every* in *everywhere*.

3.3 Adding the universal quantifier

To derive the full locative universal indefinite pronoun *everywhere* in its purely spatial use, we adopt an articulated nominal architecture which separates quantificational heads from the lower extended nominal projection, i.e., the DP layer (Shlonsky 1991; Matthewson 2001). That is, quantifiers such as *every*, *some*, and *any* externally merge as the head of a dominating QP (*contra* DP approaches to quantifiers Abney 1987; Larson and Marušič 2004). When the universal quantifier *every* merges as the head of QP, it takes the entire open locative extended nominal projection headed by *where*, i.e. $\text{PP} > \text{DP} > nP^{\text{EA}} > nP^{\text{CAT}} > \sqrt{N}$ as its semantic restrictor. Crucially, to prevent a type mismatch at this boundary, the locative P^0 head acts semantically

2. An alternative tradition, originating with Kratzer and Shimoyama (2002) for Japanese indeterminate pronouns and extended to *wh*-fronting languages by Cable (2010), treats *wh*-words as denoting sets of alternatives over which higher operators (universal, existential, interrogative) quantify. Both approaches place quantificational force on a higher head; we adopt the variable-and-binding treatment for compatibility with the lambda calculus used elsewhere in the analysis.

as an identity function ($\lambda P_{\langle e,t \rangle}.P$), passing the $\langle e, t \rangle$ type of the DP upward to the PP level unchanged, thereby providing the exact semantic type required by Q^0 .

The spatial restriction is not obligatory, but when present it is provided by a locative PP, e.g., *in the UK*, which merges as an adjunct to the outer edge of the nP^{EA} projection, as shown in (20). Following Adger (2003), we assume that prepositional modifiers within the nominal domain structurally adjoin to the outermost nP projection.

(20)

3.4 Morphological coherence: Q-to-P lowering at PF

While the syntax developed in §3.3 establishes the hierarchical relationship necessary for binding ($Q > P > D$), the components of *everywhere* are morphologically realised as a single lexical unit, i.e. a word that resists syntactic interruptions (21). While we proposed that *where* itself is formed via a syntactic incorporation process (see Baker 1988) involving leftward head-adjunction, this approach cannot be used to explain the process which gives rise to the morphological cohesion of *every+where*. A narrow-syntactic head-movement approach to incorporation of P^0 to Q^0 would incorrectly predict a suffixal linear order (**where-every*) which is ruled out under the Mirror Principle (Baker 1985a,b, 1988).

(21) *every exactly where

We argue that a post-syntactic Lowering operation at PF (Embick and Noyer 2001) is the final step creating a cohesive complex morphological lexeme. The process proceeds as follows: the higher Q^0 head lowers and adjoins to the head of its complement P^0 at PF via M-merger (Morphological Merger), which thus captures the linear order *every-wh-ere* and guarantees its realisation as a coherent portmanteau.

Overall, the analysis distinguishes two displacement operations: syntactic upward incorporation (cf. Baker 1988) of D^0 to P^0 and post-syntactic Lowering (cf. Embick and Noyer 2001) of Q^0 to P^0 . This split is not simply a stipulative fix to a morphological problem, since the operations target different elements. First, the incorporation analysis is motivated for the indefinite/interrogative r-pronoun *where*; whether it extends to other r-pronouns remains open.

More generally, the idea that indefinites, pronouns, r-pronouns, determiners, and demonstratives decompose into several parts is well established (*inter alia* Haspelmath 1997; Déchaine and Wiltschko 2002; Kayne 2005; Leu 2015). Second, Q-head Lowering at PF may apply beyond *everywhere* in morphologically complex indefinite pronouns.

The operational split reflects divergent requirements of the LF and PF interfaces, following the standard Y-model architecture (Chomsky 1995; Embick and Noyer 2001). D^0 -to- P^0 incorporation must be in the narrow syntax because it carries structural consequences, blocking external determiners such as **this where place*. In contrast, the universal quantifier Q^0 must remain higher than the compositional complex D+P head in the narrow syntax in order to c-command the extended nominal projection and bind the locative variable at LF. Lowering must take place at PF, because narrow syntactic downward incorporation would bleed Q^0 's ability to scope over *where*. Lowering at PF thus permits Q to remain in a high structural position for semantic composition at LF while satisfying the morphological well-formedness condition that *everywhere* forms an uninterruptible M-word.

4 Institutional *everywhere*: Locative syntax and institutional interpretation

We turn now to the institutional use of *everywhere* in a sentence like (22):

- (22) *Everywhere* (in London) accepts Visa these days. (Reading: every shop/business)

Sluckin and Kastner (2026) propose that the institutional reading is licensed when the discourse or the predicate supplies an Austinian topic situation (Kratzer 2019), making a contextually D-linked set of institutional referents available (Pesetsky 1987). We adopt this view, but keep the formal commitment modest: the institutional reading is a contextual interpretation of an otherwise locative nominal structure.

Institutional *everywhere* shares the internal syntactic structure detailed in (20). It maintains $\sqrt{\text{PLACE}}$ and the structurally optional PP adjunct. It does not contain $\sqrt{\text{PERSON}}$, nor does it require a relational n^{CAT} bearing [uPlace]. The institutional interpretation arises when a predicate such as *accept Visa* places sortal pressure on a locative expression: the predicate is naturally satisfied by shops, businesses, or other institutional entities, while the baseline DP contributes a spatial property. Context can resolve this pressure by mapping salient places to institutions located there.

This is compatible with predicate transfer in the sense of Nunberg (1995) and type coercion in the style of Asher (2011). For present purposes, the key point is structural: the transfer applies to the interpretation of the locative nominal restrictor without changing the narrow syntax. The DP remains built from $\sqrt{\text{PLACE}}$.

Treating the institutional use as a contextual sortal shift over unchanged locative syntax yields four useful contrasts with the impersonal use. First, the PP remains optional. It mod-

ifies the locative base rather than satisfying [uPlace] on a relational categoriser. Secondly, institutional *everywhere* shows **pronoun flexibility** in binding. Singular *its* and plural *their* are both possible because the institutional referent may be construed either as a single institutional entity or as a plural set of institutions. Thirdly, the institutional reading is subject to **cancellability**. Following [Sluckin and Kastner \(2026\)](#), acceptable sentences provide a topic situation via context or predicate entailment, as in (23a,b). Without such a situation, the institutional construal fails, as in (23c).

- (23) a. **Predicate entails shops/businesses**
Everywhere takes credit cards.
- b. **Context entails public authorities**
 In the build-up to the war, *everywhere* built air-raid shelters.
- c. **No reconstructable topic situation**
 #/**Everywhere* loves a shower. (ex. 13 [Sluckin and Kastner 2026:6](#))

Finally, a **copredication restriction** (see [Pustejovsky 1995](#); [Asher 2011](#)) obtains under the institutional reading of *everywhere*, which resists simultaneous locative and institutional predication.

- (24) #*Everywhere* is hilly and accepts Visa.

The failure of copredication is consistent with the transfer analysis. Once the institutional interpretation has been obtained, the QP behaves as an institutional expression and cannot act as a flexible place/institution complex. On this analysis the spatial variable is existentially closed: the locative variable serves only to identify the relevant institutional referent and is not itself projected as the matrix-level denotation. The QP can therefore satisfy an institutional predicate, but it cannot simultaneously serve as the argument of an ordinary spatial predicate.

These diagnostics do not merely label two readings, but show that the institutional reading is licensed by predicates and contexts that make institutions salient, permits *its* or *their* depending on construal, and does not require a human bound variable. The impersonal diagnostics introduced above point in the other direction: the construction requires *they/their* on the impersonal reading, rejects *it/its*, and patterns semantically with human quantifiers while retaining locative morphology.

The institutional use thus provides a contrast case for the impersonal analysis. Taken together, the diagnostics motivate two derivational routes rather than a single underspecified lexical item: institutional *everywhere* is $\sqrt{\text{PLACE}}$ plus a contextual/institutional interpretation over locative syntax, while impersonal *everywhere* requires $\sqrt{\text{PERSON}}$ under relational n^{CAT} .

5 The proposal: Selection of $\sqrt{\text{person}}$

5.1 From locative domains to human inhabitants

Our proposal builds on Brody (2013)’s observation that locatives can support covert human arguments. Sentences such as (25) permit an impersonal reading of *they* despite the absence of an overt plural antecedent.

(25) In Italy, they like to take a nap in the afternoon. (ex. 4, Brody 2013:34)

Brody argues that the locative expression licenses an implicit semantic human argument, conceptually a generic collective or PEOPLE. The spatial expression provides an anchor for this silent human cohort because geographical and institutional locations naturally host inhabitants. We take this as independent evidence that spatial and human categories can be grammatically linked.³

Brody’s mechanism is not by itself an analysis of impersonal [*Q+where*]. First, the human variable in impersonal *everywhere* behaves as part of the quantified subject itself: it controls, binds pronouns, and contrasts with institutional *its*. Second, the construction is tied to the internal morphology of *where*-based quantifiers rather than to an ordinary locative PP in the clause. Third, the contrast between impersonal and institutional readings requires a structural distinction between human and place/institutional restrictors.

The analysis below therefore preserves Brody’s insight but relocates it inside the nominal projection. The locative domain does not merely license a free-standing contextual PEOPLE variable; in the canonical impersonal construction it saturates a relational nominal structure whose individual variable is human.

5.2 The core impersonal derivation

The formal derivation of the impersonal structure runs as follows. Although the institutional, locative, and impersonal uses are linearly similar, impersonal generic *everywhere* is generated by a distinct nP-level derivation. The extended nominal projection remains topped by a PP, following Grimshaw (2005), with D incorporating into P (Baker 1988): silent D *wh*- head-moves into P *-ere*, deriving *where*. The QP layer hosts *every*, with the same Q-to-P lowering at PF established in §3.4. The surface locative morphology therefore remains constant while the lower nominal structure changes. The impersonal derivation differs from the locative derivation in three respects:

1. The numeration selects the unpronounced sortal root $\sqrt{\text{PERSON}}$ rather than the sortal root $\sqrt{\text{PLACE}}$, embedded under a relational categorising head n^{CAT} . This extends Kayne’s

3. Landau (2010b) argues for a syntactic link between spatial PPs and human experiencer arguments, on which experiencers are introduced under a locative P-shell. The present analysis exhibits a structurally parallel dependency in the nominal domain.

(2005) and Corver’s (2008) silent N_{PERSON} , also discussed in semantic terms by Brody (2013) in his work on pseudo-impersonals.

2. The locative PP restrictor merges in $\text{Spec}, nP^{\text{CAT}}$ rather than as a high nP^{EA} adjunct. Merge of the PP is driven by a c-selectional feature $[\text{uPlace}]$ on n^{CAT} .
3. Because the relational nP^{CAT} structure denotes a human inhabitant relation, the individual variable (λx) licensed by n^{EA} resolves to a human referent.

The formal analysis below targets the overt-PP construction, the empirical case around which the experimental generalisation is built. Marginal cases in which the locative domain is recovered from discourse or from relative-clause material are discussed separately below. These cases may require a weaker domain-recovery analysis or a repair structure, but they do not replace the $[\text{uPlace}]$ analysis of the PP construction.

The impersonal derivation is selected for generic or existential reference to human inhabitants of a subdivisible geographic location. It is unavailable in the PP construction when the predicate is incompatible with a $[\text{+HUMAN}]$ subject, when no overt PP can value $[\text{uPlace}]$ on n^{CAT} , or when the PP fails the macro-geographic interface condition on the inhabitant relation. The construction is therefore structurally less complex than *everyone everywhere in X* (Sluckin and Kastner 2026): a single QP contains a silent human root embedded under a relational categoriser.⁴

The resulting structure is given in (26).

(26)

The tree in (26) represents this division of labour by showing λx on n^{EA} and $[\text{uPlace}]$ on n^{CAT} ; the place argument is supplied by the PP rather than abstracted over by n^{EA} .

4. Following Sluckin and Kastner (2026), we use the descriptive term *PP restrictor* for the overt locative PP. Formally, however, the PP is not itself the restrictor of Q^0 : it saturates the place argument introduced by relational n^{CAT} , and the resulting human property is abstracted over by n^{EA} to form the restrictor for Q^0 .

5.3 Building the Base: $\sqrt{\text{person}}$, the Relational Categoriser, and the [uPlace] Feature

5.3.1 Syntactifying implicit person

The bridge in §5.1 motivates a connection between locative domains and human inhabitants, but it does not yet provide the internal syntax of impersonal *everywhere*. We syntactify Brody’s insight by locating the human-descriptive content in the nominal spine, implementing this via the unpronounced-nominal architecture of Kayne (2005) and the silent N_{PERSON} of Corver (2008).⁵

Kayne’s silent-noun programme allows interpretively active nominals (NUMBER, PLACE, etc.) to go unpronounced under recoverability (Kayne 2005, 2015). Within this framework, Corver (2008) argues for a semi-lexical silent noun PERSON (in the sense of Emonds 1985), active in hidden possessive constructions such as (27):

- (27) a. *We kwamen **Anna’s** tegen.*
 we met Anna-s PRT
 ‘We met Anna.’

b.

(Corver 2008:1,34)

Corver’s (2008) silent noun is licensed by an interpretable [+PERSON]/[+HUMAN] feature on the possessor. His diagnostics identify PERSON as semi-lexical rather than a full lexical N: it resists attributive modification, plural marking, and coordination.⁶

We adopt Corver’s empirical motivation for a silent human-descriptive primitive but recast it in DM-style terms: Corver’s semi-lexical N PERSON corresponds here to a silent sortal root $\sqrt{\text{PERSON}}$ categorised by n^{CAT} . The extension to impersonal *everywhere* involves one distributional difference and two theoretical claims. Distributionally, it lacks overt morphological exponence (unlike Corver’s optional *persoon*). Theoretically, the categoriser is *relational* (bearing [uPlace]) and thus narrowly c-selects an obligatory spatial PP. The silent root $\sqrt{\text{PERSON}}$

5. Brody (2013:40) also touches on the comparison with Kayne’s silent-nominal framework but leaves it as a suggestive parallel rather than a structural derivation.

6. Kayne (2005) does not assume null PERSON for universal indefinite pronouns such as *everyone*, *everybody*; these are overt realisations of the root.

contributes human-descriptive content; the relational structure lives entirely on the categoriser. Keeping these contributions on distinct terminals also matters morphologically: under the Morpheme-Locus logic assumed below, n^{CAT} supplies relational structure and conditions exponence, while $\sqrt{\text{PERSON}}$ supplies the sortal human content independently motivated by Corver/Kayne-style silent nominals.⁷

5.3.2 A multi-layered interaction

Following Borschev and Partee (2001:6), we distinguish simple sortal nouns, which denote 1-place properties, from relational nouns, which possess an internal argument place. In baseline locative *everywhere*, $\sqrt{\text{PLACE}}$ is sortal and projects no obligatory dependent. The root $\sqrt{\text{PERSON}}$ is likewise inherently sortal—denoting the descriptive content of being a person—but in the impersonal construction, it composes with a relational categoriser n^{CAT} to yield a 2-place inhabitant relation.

By locating relationality on the functional structure rather than the root (see Adger 2013), the composition $n^{\text{CAT}}(\sqrt{\text{PERSON}})$ denotes a 2-place relation between a person and a location. We model this on Borschev and Partee’s schema for relational nouns, further restricting the variables to specific semantic sorts (cf. Borschev and Partee 2001:12) to capture the strict structural requirements of the impersonal construction:

$$(28) \quad \lambda y_{\text{PLACE}}. \lambda x_{\text{PERSON}} [\text{PERSON}(x) \wedge \text{INHABITANT-OF}(y)(x)]$$

(cf. Borschev and Partee 2001:6, 12)

The predicate INHABITANT-OF is a primitive of the analysis, anchored in the overt paradigm of relational nouns such as *inhabitants*, *residents*, and *population* in (29); the macro-geographic restriction is an interface condition on when this relation yields a plausible distributed population, not a syntactic feature. Thus, before PP saturation, $n^{\text{CAT}} + (\sqrt{\text{PERSON}})$ denotes an inhabitant relation with two argument positions, y_{PLACE} and x_{PERSON} . The PP then saturates y_{PLACE} ; n^{EA} abstracts over x_{PERSON} .

Obligatory PP complements of relational nouns therefore reflect an argument introduced by structure. The impersonal *everywhere* construction follows this pattern, but the relational categoriser selects a locative PP in its specifier, rather than a nominal *of*-phrase as the complement of a lexical N or a relator phrase (for the latter see den Dikken 2006).

We formalise the locative argument via feature-driven Merge. The relevant analogy is the clausal *vP* domain, where intermediate specifier positions can license internal arguments (cf. Larson 1988; Pykkänen 2008; Alexiadou and Schäfer 2011). Specifically, to satisfy the strict Locality of Categorization (Embick 2010, 2015), n^{CAT} first merges with $\sqrt{\text{PERSON}}$ as

7. The c-selectional feature might be decomposable into [uP] and [uLOC], in line with Adger (2014). Locative pro-forms (*here*, *there*) potentially satisfy both subfeatures under the Kayne-style PP analysis adopted here (Kayne 2005); their exclusion follows from an encyclopedic size restriction, not from c-selection.

its complement. The uninterpretable [uPlace] feature on the categoriser then triggers the subsequent merge of a locative PP in $\text{Spec}, n\text{P}^{\text{CAT}}$.⁸

This configuration establishes a Spec-Head relation, valuing [uPlace] and providing the spatial variable (y) associated with the inhabitant relation. Nothing hinges here on whether the dependency is implemented as Spec-Head valuation or as a version of reverse Agree: the relevant point is that the selected locative PP locally values the place feature of relational n^{CAT} . At the interpretive interface, this formal dependency identifies the denotation of the PP with y_{PLACE} , the open place argument of the inhabitant relation; it is not a separate syntactic projection. It also keeps the selected PP low: the PP is part of the relational nominal base, rather than an adjunct added after the human variable has already been introduced.

Overt inhabitant-class nouns display a parallel need for local saturation, morphologically marked in English by *of*:

- (29) a. the inhabitants *(of London).
 b. the residents *(of this building).
 c. the population *(of Italy).

Borschev and Partee (2001) treat such nouns as 2-place predicates, with the *of*-PP supplying the internal argument. Impersonal *everywhere* shares this requirement for local saturation but differs formally: the root is unpronounced, and n^{CAT} selects a spatial PP (*in*, *on*) rather than an *of*-phrase.⁹

The derivation therefore projects a site for the locative argument, which Sluckin and Kastner (2026) call a ‘restrictor’. In this core overt-PP derivation, if the PP is absent, [uPlace] on n^{CAT} remains unvalued, giving rise to the syntactic contrast with locative *everywhere*.

The lower nP thus contains two variables: the internal spatial location (y) and the external individual variable (x). The locative PP saturates y , yielding a property of individuals. Subsequently, n^{EA} merges as the nominal locus of the referential argument (the R-role) (Roberts 2019) and abstracts over x , making the resulting human property available as the restrictor for Q^0 (*every*).

5.3.3 Morphological spell-out of *where* (and not *who/one/person*)

If the numeration selects $\sqrt{\text{PERSON}}$, why does the structure surface as *where* rather than *who*, *person*, or *everyone*? The answer, in Distributed Morphology, cannot be that the higher spatial shell overwrites the lower root. Vocabulary Insertion targets terminal nodes individually; every

8. An alternative within contemporary DM severs argument introduction from categorising heads entirely, entrusting it to dedicated low functional argument introducers, e.g. *i** (see Wood and Marantz 2017). Our proposals are compatible with such a model; we maintain a feature-driven n^{CAT} analysis for representational economy.

9. Equivalent syntactic implementations include an Adgerian c-selectional feature on the categorising n above the noun (Adger 2003, 2013) or a Relator Phrase mediating the predicative relation (den Dikken 2006: not adopted here). We remain neutral among these.

terminal is an independent locus for insertion (the Morpheme-Locus Effect; Halle and Marantz 1993; Embick 2015), and a higher P^0 cannot erase, absorb, or rewrite a lower root across a cyclic boundary (Embick and Marantz 2008). The form *where* spells out the functional shell. The silence of $\sqrt{\text{PERSON}}$ has to be explained on different grounds.

That silence is the result of local contextual allomorphy. We assume, following Embick and Marantz (2008) and Embick (2015), that roots admit contextual allomorphy conditioned by their categorising heads, including zero exponents. As argued in §5.3, the impersonal derivation embeds the human-descriptive root $\sqrt{\text{PERSON}}$ as the sister of a relational categoriser n^{CAT} ; this is where root exponence canonically takes place (Embick 2010). The impersonal construction thus involves a zero exponent for $\sqrt{\text{PERSON}}$ conditioned by the categoriser:

- (30) a. $\sqrt{\text{PERSON}} \leftrightarrow \emptyset / \text{---} n^{\text{CAT}}_{[\text{REL}]}$ (relational categoriser)
 b. $\sqrt{\text{PERSON}} \leftrightarrow \textit{person/people}$ (elsewhere)

The trigger is the identity of the relational categoriser, not the higher PP shell. This keeps the conditioning local and available at Spell-Out. The restriction to locative-restrictor contexts is derived independently in the syntax: $n^{\text{CAT}}_{[\text{REL}]}$ bears [uPlace] by specification and consequently requires Merge of the overt locative PP in $\text{Spec}, nP^{\text{CAT}}$. The zero exponent is confined to exactly that configuration. Outside it, the root falls under the elsewhere condition (or Subset Principle) (cf. Kiparsky 1973; Halle and Marantz 1993): under a default sortal n the root surfaces overtly, as in *the person*. Were this categoriser not to condition a zero exponent, Vocabulary Insertion would realise the root overtly alongside the overt PP shell, giving rise to the ungrammatical **where person*.

With the root locally unpronounced, the overt morphology of the higher functional shell is realised alone. As established for the canonical locative use of *where* (§3), the extended nominal projection is topped by spatial P^0 , into which D^0 incorporates, and the D/P complex spells out as a portmanteau. In contrast, the choice between $\sqrt{\text{PLACE}}$ and $\sqrt{\text{PERSON}}$ is made in the lower nominal domain and is morphologically invisible, i.e. it is orthogonal to P^0 . The root is syntactically and semantically active, but phonologically null because its local categoriser conditions a zero exponent.

The silence of $\sqrt{\text{PERSON}}$ reflects independently motivated structure. The relational categoriser n^{CAT} is required on grounds independent of exponence, i.e. it bears [uPlace] which forces the locative PP, and projects the inhabitant relation; the root $\sqrt{\text{PERSON}}$, however, is independently active, supplying the [+HUMAN] content behind *they/their* binding (§2.5). Zero exponence is one reflex of this configuration, not its sole motivation, and the rule is non-vacuous: under a default sortal categoriser the same root surfaces overtly (*the person, people*). Root allomorphy conditioned by a local category-defining head, zero exponence included, is standard in the framework (Embick and Marantz 2008; Embick 2010).

5.4 Interface-mediated Constraints: Quantification, Location, and Predication

5.4.1 Encyclopedic knowledge and sortal restrictions

As established by [Sluckin and Kastner \(2026\)](#), the PP in the canonical construction must denote a large-scale geographical location. We model this in two steps. The syntactic feature [uPlace] guarantees only that the PP denotes a place; it does not encode size. This division is independently motivated by the fact that small places, large places, buildings, restaurants, and countries are all syntactically locative PP domains. A simple locative feature would therefore wrongly treat them alike. While the narrow syntax forces the presence of the locative PP to value [uPlace], the macro-geographic size constraint is not encoded as a formal syntactic feature. We assume a standard generate-and-filter architecture at the syntax-semantics interface (see e.g., [Preminger 2014](#); [Borer 2005a,b](#)). Structurally well-formed nominals are generated in the syntax and subsequently evaluated against encyclopedic conditions on the inhabitant relation. Micro-locations fail this post-syntactic filter because they cannot conceptually host a socially and geographically distributed inhabitant population suitable for generic quantification (31).

(31) *#everywhere* in the building helps out in the communal garden

This contrasts with the implicit PEOPLE argument associated with *they* in locative contexts (cf. [Brody 2013](#)). Impersonal *they* can be pragmatically associated with smaller domains because the locative PP remains a clausal or contextual anchor. In canonical impersonal *everywhere*, by contrast, the PP is inside the nominal restrictor of quantification as the local argument of relational n^{CAT} . The domain must therefore be suitable as the restrictor for a human quantifier, not merely locative in syntax. The restriction is a property of the nominal architecture of *everywhere*, not a general property of locative PPs.

(32) In Italian restaurants, they make good pasta.

5.4.2 Genericity and quantificational variation

To capture the distribution of impersonal *where*-based pronouns, we pursue a DP-internal analysis of quantificational force. This avoids the tension that a clausal GEN operator would create with existential and negative forms such as *somewhere* and *nowhere*. Quantificational force comes from Q^0 : *every* introduces universal quantification ($\forall$), binding the human variable licensed by n^{EA} . The episodic judgements in this subsection are exploratory author judgements pending systematic testing; the structural claim is only that the same lower nominal structure can occur under different Q-heads.

The layered nP complex provides a human variable (λx), while the spatial restrictor (y) constrains the domain pragmatically. Following [Von Stechow \(1994\)](#), quantificational domains are systematically constrained by contextual variables. Here the variable is interpreted through an

inhabitant relation ($\text{INHABITANT-OF}(y)(x)$), so the quantifier ranges over spatially organised human individuals rather than over an unrestricted set of persons.

This spatial organisation is compatible with the construction's generic interpretation. Because *everywhere* is evaluated over a geographically distributed restrictor, localised episodic events are often pragmatically disfavoured: in ordinary contexts, it is implausible for a single event to involve all relevant inhabitants across the domain. Episodic predicates are therefore not structurally banned, but they require a context supporting distributed experience across a macro-geographic domain, as in (33).¹⁰

- (33) a. *Everywhere* in the country felt the earthquake.
 b. *Everywhere* in the world watched the moon landing.

Without such a distributed event, the matrix predicate tends towards a characterising reading (Krifka et al. 1995), such as a cultural habit or environmental response (34). This is a preference created by the spatially distributed restrictor, rather than an independent generic operator in the clause. We use *characterising* for a stable or generalising property of the subject rather than a single spatio-temporally bounded event. The preference is graded and context-dependent, not categorical: distributed events such as those above remain possible.

- (34) *Everywhere* in the Netherlands rides bicycles.

Somewhere: Replacing universal *every* with existential *some* weakens these restrictions: a localised event need not hold across all subdomains. Existential *somewhere* therefore appears compatible with localised episodic predicates, provided the same nominal structure is available. Because the relevant location is not identified, the resulting reading often has an epistemic flavour (35).

- (35) a. Somewhere in the world must be awake at this hour.
 b. Somewhere in the city must be freezing in this rain.

Nowhere: With negative *no* in Q^0 , the construction places negation over the relevant spatially organised domain. Since the absence of an event does not require a simultaneous pluralisation of a given event, i.e. there is no positive requirement that everyone in the defined domain does or is doing *x*, episodic *nowhere* seems more flexible than *everywhere*. The judgements are still preliminary, but examples such as (36) suggest that both habitual/generic and episodic predicates are available.

- (36) a. Nowhere in Europe eats fermented frogspawn.
 b. Nowhere in the country is rioting right now.
 c. Nowhere in Europe is experiencing power cuts today.

10. Author's own judgement.

Anywhere: The polarity-sensitive variant *anywhere* instantiates the same structure with *any* in Q^0 . Following Dayal (1998), *any* may be treated as a universal quantifier with modal force, and its distribution as an impersonal subject is compatible with the standard restriction to non-veridical contexts (Giannakidou 1998). Under negation and in interrogatives (37a,b), the characterising-predicate preference of positive *everywhere* (§5.4) is plausibly weakened because these operators block an assertion of a real-world temporally simultaneous universal event.¹¹

In positive unembedded contexts, the Free-Choice use of *anywhere* may avoid an episodic clash via subtriggering (see Dayal 1998), as in (37c), where the relative clause supports the needed situation variation. This preserves the same lower nominal structure while shifting the licensing conditions to the QP and its environment.

- (37) a. I don't think anywhere in the country is watching the playoffs right now.
 b. I wonder if anywhere in the UK is watching the playoffs.
 c. Anywhere in England that eats oysters is probably by the sea.

Summary: Across *everywhere*, *somewhere*, *nowhere*, and *anywhere*, quantificational variation is localised at Q^0 , not on a higher GEN operator. The nominal structure remains constant: $\sqrt{\text{PERSON}}$ remains sortal, n^{CAT} remains relational and bears [uPlace], and the PP remains in $\text{Spec}, nP^{\text{CAT}}$. What varies is the force contributed by Q^0 and its pragmatic interaction with spatial distribution.

5.5 Ruling out Lexical Polysemy: Coercion and Dot-Objects

One might alternatively hypothesise that impersonal *everywhere* retains a spatial root ($\sqrt{\text{PLACE}}$) and receives its human interpretation through lexical polysemy or metonymy. A dot-object analysis in the style of Pustejovsky (1995), for instance, could treat $[n^{\text{CAT}} + \sqrt{\text{PLACE}}]$ as a complex $\text{PLACE} \bullet \text{HUMAN}$ object whose spatial and human facets are both available. This would make the construction closer to ordinary place-for-inhabitant metonymy. The strongest pressure against this view comes from copredication (see e.g., Cruse 1986; Asher 2011). If the pronoun behaved like overt geopolitical entities that permit spatial and human predicates together, as in (38), coordination should be relatively natural. Yet with physical or biological human predicates, simultaneous copredication is zeugmatic:

- (38) The city is polluted and voted Green
- (39) a. $\#[\text{Everywhere in the Netherlands}]_i$ is completely flat and t_i rides bicycles to work.
 b. $\#[\text{Everywhere in Southern Spain}]_i$ gets incredibly hot in August and t_i takes a siesta after lunch.

11. Direct evidence for this prediction is currently limited: Sluckin and Kastner (2026) attest *anywhere* only in characterising contexts, and systematic testing of episodic predicates under negation, as in (ia), remains outstanding.

This pattern also blocks copredication in the institutional use, but for a different reason: as §4 argued, the institutional reading existentially closes the spatial variable. The impersonal pattern is instead expected if the numeration selects sortal $\sqrt{\text{PERSON}}$ under relational n^{CAT} : the spatial denotation is supplied by the selected PP, not projected by the QP itself.

The failure in (39) is suggestive rather than decisive, since conventionalised place-for-inhabitant metonymies such as *London votes Labour* also resist simultaneous predication. A second diagnostic comes from discourse anaphora. If the QP retained a spatial denotation, *it*-anaphora should be easier. Instead, the contrast in (40) suggests that the impersonal QP makes a human referent available, while spatial anaphora must target the PP restrictor or a locative use.

- (40) a. Everywhere in the Netherlands rides bicycles to work, and #it is mostly below sea level.
- b. Everywhere in the Netherlands rides bicycles to work, and they also **Impersonal** eat Frikandel with chips and mayonnaise.
- c. Everywhere in the Netherlands is flat, and it is mostly below sea level. **Spatial**

Taken together, the copredication and anaphora facts favour the discrete-root analysis over a dot-object or coercion analysis that leaves a spatial denotation active at the QP level. They do not by themselves prove that no metonymic route is ever available, but they combine with the binding profile of the construction to motivate a structural split. Institutional *everywhere* is place-based and contextually transferred; impersonal *everywhere* behaves as a human quantifier for binding and antecedence while remaining locative in its outer morphology. On the present account, this follows because the extended projection selects sortal $\sqrt{\text{PERSON}}$ together with relational n^{CAT} , while the spatial contribution is introduced by the selected PP.

5.6 Intermediate Summary

Impersonal *everywhere* spells out an extended nominal projection in which relational n^{CAT} embeds silent sortal $\sqrt{\text{PERSON}}$ and bears [uPlace], forcing a locative PP into $\text{Spec}, nP^{\text{CAT}}$. The PP supplies the spatial argument of the inhabitant relation; n^{EA} abstracts over the individual variable, yielding a human property for Q^0 .

This structure accounts for PP obligatoriness and leaves the macro-geographic profile to the interface, as argued in §5.4. The syntax fixes the presence and position of the PP; the scale restriction follows from encyclopedic knowledge of the inhabitant relation rather than from a dedicated grammatical feature.

The tendency towards characterising predicates likewise follows from the spatially organised restrictor. Predicates that hold steadily across locations fit this structure more naturally than punctual episodic events, which may resist distribution over a macro-geographic domain. This is a pragmatic-interface tendency, not a complete semantics; the analysis only requires that the

selected PP remain visible to the interpretation of the human restrictor.

Finally, copredication and discourse-anaphora diagnostics support the discrete-root analysis over a lexical-polysemy alternative.

5.7 Extensions and broader empirical coverage

5.7.1 Bound *they/their*

The construction obligatorily binds 3pl *they/their* (§2.5). Our analysis provides a human property via λ -abstraction, and quantification ranges over inhabitants of the saturating PP. Bound *they/their* follows from the indefinite, non-referential status of the bound variable, on a par with other human quantifiers (*everyone*, *nobody*, *no one*); see Huddleston and Pullum (2002) on *singular they* with quantified antecedents. The infelicity of *it/its* reflects the human-descriptive semantics of $\sqrt{\text{PERSON}}$ and is therefore expected without assigning relationality to the root. A featural treatment is beyond the scope of this paper.

5.7.2 Clausal integration: case and the EPP

The proposed nominal structure resolves the DP–locative tension raised in §1.2. The clausal subject is a QP, not a bare locative PP. This Q-layer corresponds to the high quantificational layer found in ordinary expressions such as *everyone*. We do not assume $Q = D$; however, QP and DP pattern alike for subject licensing (cf. Abney 1987). This follows if T requires a nominal extended projection rather than D specifically. This structural distinction separates impersonal *everywhere* from true locative inversion. In true locative inversion, a preverbal locative PP has been claimed to satisfy the EPP on T but fails to trigger ϕ -agreement on T (see *inter alia* Bresnan 1994; Roberts 2010). Impersonal *everywhere*, by contrast, functions as a nominal QP subject that values T’s ϕ -probe.

This valuation proceeds via direct syntactic probing. In indefinite pronoun constructions in English, we assume that quantifier heads such as *every*, *any*, *some*, *no* lack a valued ϕ -set. While quantifiers like *every* conceptually restrict their domains and semantically select singular complements, they do not project formal ϕ -features. Therefore, T’s EPPD probe bypasses Q and directly targets the incorporated D/P complex. The upward incorporation of the D head (*wh-*) into the P head (*-ere*) places nominal D-features at the same level as P, hence there is no risk of an intervention effect. These D-features then satisfy T’s EPP requirement (cf. Chomsky 1995, 2001).

The 3sg agreement on T follows directly from this configuration. T agrees with the indefinite D/P complex (*where*), which we consider inherently underspecified for number as an indefinite. Therefore, the morphology inserts the 3sg affix via elsewhere realisation (Halle and Marantz 1993).¹²

12. For related treatments of agreement with deficient or underspecified goals, see Preminger (2014).

5.7.3 The subject restriction: a Subject-of-Predication dependency

The clausal-integration account in §5.7.2 explains how impersonal *everywhere* satisfies T's formal EPP and agreement requirements, but not why the impersonal reading is confined to subject-like positions. If *everywhere in England* were syntactically equivalent to *everyone in England*, it would distribute freely as an internal argument. It does not.

- (41) a. *Everywhere* in England loves fish and chips.
 b. # I met *everywhere* in England at the conference. ***impersonal**

The restriction is not Case-theoretic. The impersonal reading is available on an accusative argument, provided that argument is the subject of a predication: Sluckin and Kastner (2026) report it in ECM and small-clause environments, where the bound pronoun is impersonal-human *their*, not institutional *its* (§2.5).

- (42) Thanks to constant news coverage, the Queen watched *everywhere* in the UK enjoying (their) street parties for the Jubilee celebrations. (ex. 22, Sluckin and Kastner 2026)

The ECM subject in (42) and the direct object in (41b) are both accusative, yet only the former, the subject of a predication, supports the impersonal reading. The conditioning factor is predication subjecthood, not Case. We capture this with the Subject-of-Predication feature [*u*δSoP] that Sluckin (2021, 2024) locates on C, extending the δ-feature system of Miyagawa (2017): [*u*δSoP] is valued under local Agree by the goal in Spec,TP. The impersonal interpretation is the SoP-licensed reading, so it is available only where *everywhere* itself occupies Spec,TP and values this feature.

The object restriction then follows from the probing analysis of §5.7.2. When *everywhere* is merged as an internal argument below a higher argument, T's D-probe targets that higher argument first; by minimality *everywhere* cannot raise to Spec,TP, [*u*δSoP] on C is left unvalued by it, and the impersonal derivation is unavailable. The silent $\sqrt{\text{PERSON}}$ is recoverable only in this configuration, so in non-subject positions *everywhere* retains only its locative and institutional construals. ECM and small-clause subjects pattern with matrix subjects because there *everywhere* is itself the highest argument of the embedded predication; its accusative Case is irrelevant to [*u*δSoP].

The mechanism makes a converse prediction. Where no argument intervenes, as in passives and unaccusatives, the internal argument can itself raise to Spec,TP and value [*u*δSoP], so the impersonal reading should be available. This is borne out for characterising predicates, while episodic counterparts are degraded (43).

- (43) a. Everywhere in Spain is/gets paid well for their work, despite taking a two-hour nap in the afternoon. **characterising**
 b. # Everywhere in Spain was/got paid well yesterday for their work, despite taking a two-hour nap in the afternoon. **episodic**

Informal consultation (the author and four further speakers) found this contrast for most speakers, with some inter-speaker variation and one speaker accepting episodics more readily under *get-* than *be-*passives. Such variation is consistent with the characterising effect being a graded preference rather than a categorical ban (§5.4). The degraded passives reported by Sluckin and Kastner (2026) are plausibly episodic; a controlled generic/episodic comparison is left for future work.

So construed, impersonal *everywhere* falls within the broader class of dedicated human impersonals such as German *man*, French *on*, and Italian *si* (Cinque 1988; Egerland 2003), which we take to be inherent subjects of predication rather than freely distributed DPs. Impersonal *everywhere* differs only in internal composition, building its human argument from a locative QP and a silent relational nominal, while sharing that defining requirement.¹³

One issue remains open within the synchronic account: the precise pragmatic conditions on episodic readings across the *somewhere/nowhere/anywhere* paradigm. This is compatible with the analysis proposed here, but is not yet fully derived.

6 Predictions and open questions

The analysis in §5 links the obligatoriness and low position of the PP to [uPlace] on n^{CAT} , treats macro-geographic scale as an interface condition on the inhabitant relation, connects full-DP behaviour and *they/their* binding to the [+HUMAN] semantics of $\sqrt{\text{PERSON}}$ (§5.7), and relates quantificational variation to Q^0 . Three further issues require comment: coordination, restrictor reordering, and the status of relative-clause restrictors.

6.1 Coordination with *everyone*

The analysis leads us to expect that impersonal [$Q+where$] and [$Q+one$] pronouns coordinate. Both denote human properties bound by Q^0 , and coordination requires that both conjuncts match in semantic type ($\langle e, t \rangle$). This expectation is borne out in the grammaticality (author's own judgement) of the example in (44).

- (44) Everyone in London and everywhere in the rest of the UK eats fish and chips.

A property-of-places analysis that obtains the impersonal reading by metonymic coercion does not naturally capture (44): it requires asymmetric type-shifting on one conjunct. Additional experimental testing of this and further such coordinations is needed to provide a stronger empirical argument.

13. This Subject-of-Predication licensing is distinct from the covert-perceiver analysis of locative inversion in Sluckin (2024), where the preposed locative is itself the subject-like element; both motivate a decomposition of English subjecthood but involve different silent elements.

6.2 Restrictor reordering

The PP restrictor appears in three positions:

- | | | | |
|------|----|--------------------------------------|----------------------------|
| (45) | a. | Everywhere in the UK loves Marmite. | base order |
| | b. | In the UK, everywhere loves Marmite. | fronted PP |
| | c. | Everywhere loves Marmite in the UK. | right-dislocated PP |

The base order in (45a) corresponds directly to the nominal structure proposed in §5. The fronted variant (45b) results from preposing the PP to the left periphery under information-structural triggers (Rizzi 1997); nothing in that structure blocks this operation.¹⁴

The rightward-displaced variant (45c) surfaces with the PP separated from its selecting head. Linearising to the right of the object requires the PP to occupy a position structurally external to the subject DP at PF. We propose an extraposition-from-DP analysis: the PP merges in Spec, nP^{CAT} to value [uPlace], satisfying the local selectional requirement, and subsequently dissociates from that position by whatever extraposition mechanism the grammar makes available. The analysis is neutral between a rightward-adjunction analysis (since Rosenbaum 1967; Guéron 1980), a remnant-leftward-movement implementation (Fox and Nissenbaum 1999; Reeve and Hicks 2017), and a purely PF-side linearisation analysis compatible with the Linear Correspondence Axiom (Kayne 1994). The commitment of the present analysis is to the external merge site of the PP, not to the directionality of its subsequent displacement.

While extraposition of a selected specifier out of a DP is structurally more restricted than the extraposition of adjuncts or relative clauses (Fox and Nissenbaum 1999), PP extraposition from subject DPs is a robust operation in English (Guéron 1980). Recent theoretical accounts argue for the availability of direct rightward movement for such dependencies (Reeve and Hicks 2017; Bruening 2018). The precise constraints on moving a valued specifier are left open here.

The alternative which we reject is the external merge of the PP as a clausal adjunct, with no narrow-syntactic relation to n^{CAT} . This would require positing a null PP inside the subject DP to saturate the relational variable and discharge [uPlace]. Such a proposal not only weakens [uPlace] as a strict c-selectional feature, but it also introduces a silent element with no independent motivation. The extraposition analysis preserves the c-selectional relation established in §5 regardless of which mechanism implements the displacement.

6.3 Relative clauses and locative domains

Relative-clause restrictors belong to the broader question of how the locative domain is realised. The hierarchy of cases is important. The core impersonal construction remains the overt-PP construction: [uPlace] on relational n^{CAT} is valued by a locative PP in Spec, nP^{CAT} . Relative clauses are considered here because Sluckin and Kastner (2026) note that $[Q + \textit{where}]$ forms are

14. Sluckin and Kastner (2026) did not test reordering experimentally but remark on its acceptability, confirmed by the author's own native-speaker judgement.

not categorically impossible with *that*-relatives. The empirical pattern is split: *who*-relatives are sharply degraded, whereas *that*-relatives are marginal, context-sensitive, and untested experimentally.

The clearest contrast concerns *who*. Ordinary human quantifiers readily take *who*-relatives, but $[Q + \textit{where}]$ forms do not.

(46) a. Everyone who knows Mary loves her.

b. *Everywhere who knows Mary loves her.

This follows from the present analysis. *Who* requires a morphosyntactically accessible human nominal head. In the impersonal $[Q + \textit{where}]$ construction, the human variable is introduced inside the lower $\sqrt{\text{PERSON}}-n^{\text{CAT}}$ complex and abstracted over by n^{EA} , but the overt shell visible to the relative system is still the *where*-projection. Its external morphosyntax is locative, not personal. The human component is therefore available for interpretation and binding, but not as the local nominal head required to license a *who*-relative.

The contrast with *that* is different. Since *that* is not specified as a human relativiser, it does not create the same immediate feature clash. Accordingly, [Sluckin and Kastner \(2026\)](#) report marginal *that*-relative cases, such as (47).

(47) a. Everyone that's heard of Mother Teresa loves her.

b. ?Everywhere that's heard of Mother Teresa loves her.

These examples suggest that relative clauses after $[Q + \textit{where}]$ cannot be ruled out across the board. The relativiser *that* avoids the feature clash created by *who*, since it does not require an overt human nominal head. But this only removes one obstacle: it does not mean that the relative CP itself supplies the locative argument required by n^{CAT} , and it does not show that CP can replace the PP in the core syntax.

The reported natural example in (48), from the show *Ted Lasso*, is also not a clean diagnostic for the impersonal construction. It involves existential *somewhere*, not universal *everywhere*, and occurs as a fragment answer to a question resuming a directional goal.

(48) **Question:** Where is she going?

Answer: Somewhere that believes they deserve her.

We do not treat (48) as a clean diagnostic for the impersonal construction. The main analysis of such marginal cases is contextual or Brody-style locative-domain recovery. On Brody's view, locative expressions can make an implicit PEOPLE argument available: a place can support reference to the people associated with it, without the locative expression itself being syntactically converted into a human nominal. The *Ted Lasso* example can therefore be understood as a locative use of *somewhere* in which the relative clause makes this associated human variable salient. It does not show a relative CP valuing the c-selectional $[\text{uPlace}]$ feature on n^{CAT} .

The limits of *that*-relatives become clearer when the relative clause must support a fully

individual-denoting impersonal subject in a matrix predicate (Sluckin and Kastner 2026).

- (49) a. Everyone that has a house looks after/loves their garden.
 b. *Everywhere* in England looks after/loves their garden.
 c. **Everywhere* that has a house looks after/loves their garden.

The contrast between (49 b,c) is telling. A locative PP restrictor licenses the impersonal reading, as in (49 b). A bare *that*-relative does not. The CP relative in (49c) cannot provide the locative place argument required by the lower relational structure. We note the final contrast in which a PP restrictor and the CP-relative are combined, which is improved; yet it is still degraded compared to the lone PP restrictor; however, this introspective judgement requires further empirical testing to be confirmed definitively.

- (50) ?*Everywhere* in England that has a house looks after their garden.

Other apparent *that*-relative cases are likewise compatible with independently available locative or institutional readings. A rare attested example from online discourse such as (51) is too ambiguous between PLACE → INSTITUTION metonymy and quantification over inhabitants to decide the issue.

- (51) Everywhere that watches Netflix is part of the US cultural empire.¹⁵

Similarly, *that*-relatives are easier when the sentence can be interpreted over places, countries, institutions, or their representatives, as in (52).

- (52) *Everywhere* that has a royal family loves its/their queen.

Such examples do not show that *that*-relatives freely license the impersonal structure; they show only that relative clauses combine more easily with independently available locative or institutional uses of *everywhere*. Institutional readings matter here only as a source of ambiguity in particular examples. The main point is that any human flavour in these cases can arise through contextual locative-domain recovery, rather than through CP saturation of [uPlace].

Relative clauses therefore do not pose a serious problem for the core analysis. The result is not a menu of alternative derivations. *Who* confirms that the externally accessible shell is locative rather than human. *That* avoids the human-relativiser clash, but it remains too weak on its own to act like the PP as a structural licensing factor for impersonal *everywhere*. The obligatory PP-restrictor construction remains the central case around which the analysis is built: this PP values [uPlace] on n^{CAT} in $\text{Spec},nP^{\text{CAT}}$ and saturates the place variable in the inhabitant relation; n^{EA} only abstracts over the resulting human variable.

A related observation comes from embedded-question contexts tested by Sluckin and Kastner (2026), where bare *where* appears with similar impersonal subject behaviour.

15. Attested example from a Hacker News discussion thread: <https://news.ycombinator.com/item?id=43278694> (accessed May 27, 2026).

- (53) a. I knew about the first one, but I don't know where in the world eats bird's nest soup.
- b. ?I knew about the first one, but I don't know where eats bird's nest soup.

Although this is an embedded interrogative rather than a relative-clause restrictor, it suggests that *where* can appear in a CP environment while retaining an impersonal-like construal. The example is suggestive, not decisive, but it makes a P/CP-mediated analysis of marginal relative-clause cases less ad hoc.

If future studies show that *that*-relatives can regularly license impersonal [*Q+where*] readings in particular environments, the most conservative extension would be a null locative P-shell, schematically [PP P⁰ [CP *that* ...]], in line with existing missing-P, PP-like free-relative, and P/C-overlap analyses (Larson 1987; Grosu 1996; Caponigro and Pearl 2008; Emonds 1985; Dubinsky and Williams 1995). This would not be part of the core derivation, as the CP itself could not value [uPlace], while the silent P-shell would preserve PP saturation in Spec,*n*P^{CAT}. The null-P-shell option is therefore a possible repair analysis for future data, not a central component of the analysis proposed for impersonal [*Q + where*], which, given the current data, remains characterised by the inclusion of an overt PP.

7 Conclusion

This paper has argued that English [*Q+where*] expressions support three distinct quantified referent types. Locative *everywhere* is built over silent $\sqrt{\text{PLACE}}$ inside a P-headed nominal projection. Institutional *everywhere* retains that locative structure, with the institutional interpretation arising through contextual predicate transfer in the sense of Nunberg (1995). Impersonal *everywhere*, by contrast, contains silent sortal $\sqrt{\text{PERSON}}$ under a relational categoriser *n*^{CAT} bearing [uPlace]. In the canonical overt-PP construction, [uPlace] is valued by a macro-geographic PP in Spec,*n*P^{CAT}, which saturates the place argument of an inhabitant relation; the higher categoriser *n*^{EA} abstracts over the human individual variable, which gives the restrictor for Q⁰.

The account preserves the external locative morphology of *where* while locating the human contribution in the lower nominal domain. Relationality is contributed by functional structure rather than by the root, in line with proposals that obligatory dependents of relational nouns are introduced structurally (Adger 2013). The construction also extends the Kaynian silent-noun programme (Kayne 2005, 2015; Corver 2008): English does not need a dedicated overt impersonal pronoun here because the relevant human variable is introduced inside the nominal structure of a *where*-based quantifier. Brody's locative-licensed PEOPLE mechanism is therefore not abandoned, but syntactified inside the extended nominal projection.

Several issues remain open. In addition to a more detailed empirical appraisal of relative-clause restrictors reserved for future exploration, the pragmatic conditions on episodic readings

across the *somewhere/nowhere/anywhere* paradigm await systematic testing. The subject restriction itself, however, we have analysed as a Subject-of-Predication effect (§5.7.3), situating impersonal *everywhere* among subject-oriented human impersonals. While the syntax fixes the presence and low position of the PP, the macro-geographic scale restriction is best treated as an interface condition on the inhabitant relation in the semantics for a domain suitable for generic quantification over a distributed population.

The broader result is a compositional account of the English [*Q+where*] paradigm. Place, institution, and human-inhabitant readings share overt *where*-morphology, but they do not share the same lower nominal structure. The construction therefore shows how silent nominal roots, relational categorisation, contextual transfer, and locative morphology can jointly determine the referential domain of a quantified expression.
